List of Tables

List of Figures

List of Attachments

List of Acronyms and Abbreviations

µg/L	micrograms per liter
µg/m^3	microgram per cubic meter
2,3,7,8-TCDD	2,3,7,8-Tetrachlorodibenzo-*p*-dioxin
4,4'-DDD	4,4'-dichlorodiphenyldichloroethane
4,4'-DDE	4,4'-dichlorodiphenyldichloroethylene
7Q10	Lowest 7-day average streamflow that occurs on average once every 10 years
AAF	Absorption Adjustment Factor
ACS	American Cancer Society
ADAF	Age-Dependent Adjustment Factor
ADE	Average Daily Exposure
Ah	Aryl hydrocarbon
ARSP	Anacostia River Sediment Project
ATSDR	Agency for Toxic Substances and Disease Registry
BAF	Bioaccumulation Factor
BaP	Benzo(a)pyrene
BERA	Baseline Ecological Risk Assessment
bgs	Below ground surface
BHHRA	Baseline Human Health Risk Assessment
BMD	Benchmark Dose
BMDL	Benchmark Dose Lower Bound
BTV	Background Threshold Value
CADD	Chronic Average Daily Dose
CalEPA	California Environmental Protection Agency
CAS	Chemical Abstracts Service
CERCLA	Comprehensive Environmental Response, Compensation, and Liability Act
cm/hr	Centimeters per hour
COC	Chemical of Concern
COPC	Chemical of Potential Concern
CSF	Cancer Slope Factor
CSM	Conceptual Site Model
CTE	Central Tendency Exposure
DAF	Dermal Absorption Fraction
DC	District of Columbia
DDx	Dichlorodiphenyltrichloroethane, Dichlorodiphenyldichloroethylene, Dichlorodiphenyldichloroethane
DOEE	Department of Energy and Environment
DPT	Direct-Push Technology
DRO	Diesel Range Organics
ELCR	Excess Lifetime Cancer Risk
EPC	Exposure Point Concentration
FOD	Frequency of Detection
FS	Feasibility Study

ft^2	square feet
ft^3/sec	cubic feet per second
ft/sec	feet per second
g/day	grams per day
GLFATF	Great Lakes Fish Advisory Task Force
HEAST	Health Effects Assessment Summary Tables
HI	Hazard Index
HQ	Hazard Quotient
IRIS	Integrated Risk Information System
K_p	Permeability Constant
LADD	Lifetime Average Daily Dose
LMS	Linearized Multistage
LOAEL	Lowest Observed Adverse Effect Level
LWZ	Lower Water-bearing Zone
m^3/kg	cubic meters per kilogram
MCL	Maximum Contaminant Level
MDE	Maryland Department of the Environment
$mg/cm^2/hr$	Milligrams per square centimeter per hour
mg/cm^3	Milligrams per cubic centimeter
mg/kg	Milligrams per kilogram
mg/kg-day	Milligrams per kilogram of body weight per day
mg/m^3	Milligrams per cubic meter
MRL	Minimal Risk Level
MTBE	Methyl tert-butyl ether
NCEA	National Center for Environmental Assessment
NCP	National Contingency Plan
NOAA	National Oceanic and Atmospheric Administration
NOAEL	No Observed Adverse Effect Level
NPS	National Park Service
NRWQC	National Recommended Water Quality Criteria
OSWER	Office of Solid Waste and Emergency Response
PAH	Polycyclic Aromatic Hydrocarbon
RBA	Relative Bioavailability Factor
PCB	Polychlorinated Biphenyl
PEF	Particulate Emission Factor
POD	Point of Departure
PPRTV	Provisional Peer Reviewed Toxicity Values
QAPP	Quality Assurance Project Plan
QC	Quality Control
RAGS	Risk Assessment Guidance for Superfund
RBSL	Risk-Based Screening Level
ReP	Relative Potency
RfC	Reference Concentration
RfD	Reference Dose
RI	Remedial Investigation
RME	Reasonable Maximum Exposure
RPD	Relative Percent Difference

RPF	Relative Potency Factor
RSL	Regional Screening Level
SAB	Science Advisory Board
SRC	Syracuse Research Corporation
SVOC	Semivolatile Organic Compound
TEF	Toxicity Equivalency Factor
TEQ	Toxicity Equivalence
TPH	Total Petroleum Hydrocarbon
UCL	Upper Confidence Limit on the Mean
UF	Uncertainty Factor
URF	Unit Risk Factor
USEPA	United States Environmental Protection Agency
USFWS	United States Fish and Wildlife Service
USGS	United States Geological Survey
UWZ	Upper Water-bearing Zone
VDEQ	Virginia Department of Environmental Quality
VISL	Vapor Intrusion Screening Level
VOC	Volatile Organic Compound
WHO	World Health Organization

1 Introduction

1.1 Background

AECOM has prepared this Baseline Human Health Risk Assessment (BHHRA) on behalf of Potomac Electric Power Company (Pepco) and Pepco Energy Services, Inc. (collectively "Pepco") to evaluate potential human health risks associated with Pepco's Benning Road Facility (the Site), located at 3400 Benning Road NE, Washington, DC, and a segment of the Anacostia River (the River) adjacent to the Site. The general location of the Site is shown on **Figure 1-1**. The 77-acre Site is defined by the property boundary shown on **Figure 1-2**. Together, the Site and an adjacent segment of the River are referred to herein as the "Study Area." Pepco performed the Remedial Investigation/Feasibility Study (RI/FS) pursuant to the requirements of a consent decree with the District of Columbia (DC) that was entered by the U.S. District Court for the District of Columbia on December 1, 2011 (the Consent Decree).

The RI/FS Study Area investigation consists of a "Landside" component focused on the Site itself, and a "Waterside" component focused on the shoreline and sediments in the segment of the River adjacent to and immediately downstream of the Site (aa area of approximately one-half mile of shoreline). The Landside and Waterside Investigation Areas are depicted on **Figure 1-2**.

Pepco submitted the Draft RI/FS Work Plan to the Department of Energy and Environment (DOEE) in July 2012 and made subsequent revisions to address comments from DOEE and the public. The BHHRA Work Plan was included as Appendix E of the Draft RI/FS Work Plan. DOEE provided final approval for the Work Plan in December 2012 (AECOM, 2012). During 2014, two addenda to the RI/FS Work Plan were prepared to describe supplemental Phase I RI field investigation activities; these were approved by DOEE in March and July 2014 (AECOM, 2014a, 2014b). The 2012 approved work plan and the two addenda formed the basis for the Phase I RI.

The Draft RI Report, which describes the Phase I field investigation and its findings, was finalized on February 26, 2016 (AECOM, 2016a). A preliminary BHHRA was included as Appendix Z of the Draft RI Report. The Draft RI Report was made available for public comment from March 01, 2016 through April 18, 2016. A response to public comments was prepared and released to the public in August 2016. The Draft RI Report identified several data gaps with respect to the Phase I Site characterization, background data evaluation, and human health and ecological risk assessments. Per DOEE's RI Path Forward letter of January 14, 2016, Pepco prepared three technical memoranda to further define data needs and prepare for additional site characterization. The Technical Memorandum #1 – Conceptual Site Model

(CSM) (AECOM, 2016b) provided a detailed description of the operational Site history, with a focus on the use, storage, disposal, release, and cleanup of various chemicals and waste materials, and identified data gaps and uncertainties in the Study Area characterization conducted to date as part of the RI/FS. The Technical Memorandum #2 – Refined Background Evaluation Work Plan (AECOM, 2016c) described the rationale and procedures for revising the background data evaluation originally presented in the Draft RI Report. The Technical Memorandum #3 – Baseline Human Health and Ecological Risk Assessment Work Plan (AECOM, 2016d) described the rationale and procedures for revising the preliminary BHHRA and preliminary baseline ecological risk assessment (BERA) originally presented in the Draft RI Report. The three technical memoranda were approved by DOEE in October 2016.

Work Plan Addendum #3 (AECOM, 2016e) was developed in conjunction with the three technical memoranda to detail the Phase II field investigation to address the remaining data gaps and uncertainties identified. Work Plan Addendum #3 was approved by DOEE in October 2016 and formed the basis for the Phase II RI.

A Draft Final RI Report was finalized in September 2019. The Draft Final RI Report was made available for public comment from October 4, 2019 through December 6, 2019. This Final RI Report incorporates the public comments received during the comment period.

Consistent with United States Environmental Protection Agency (USEPA) guidance (2002a, 2005a), a risk-based framework has been adopted for this RI/FS. This framework utilizes an iterative approach coupled with Site-specific information to define the conceptual site model, assess potential risks, and evaluate further actions. The use of Site-specific information is consistent with principles articulated by the National Research Council of the National Academy of Sciences (NRC, 2001) and USEPA guidance on risk assessment and risk management decision-making at contaminated sites (USEPA, 1989a, 2002a, 2005a, 2011, 2014a).

1.2 BHHRA Methodology

This revised BHHRA was performed in accordance with the DOEE approved Risk Assessment Work Plan and Addendum (AECOM, 2012, 2016d).

In the absence of DOEE-specific guidance, and as discussed with DOEE staff, the BHHRA was conducted to comply with USEPA guidance for conducting a risk assessment including, but not limited to, the following:

- Risk Assessment Guidance for Superfund (RAGS): Volume 1 - Human Health Evaluation Manual (Part A) (USEPA, 1989a);

- Role of the Baseline Risk Assessment in Superfund Remedy Selection Decisions. Office of Solid Waste and Emergency Response (OSWER) 9355.0-30. April 1991 (USEPA, 1991);
- Guidance for Data Usability in Risk Assessment (Part A) (USEPA, 1992a);
- Guidelines for Exposure Assessment (USEPA, 1992b);
- Land Use in the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) Remedy Selection Process (USEPA, 1995);
- Calculating Upper Confidence Limits for Exposure Point Concentrations at Hazardous Waste Sites (USEPA, 2002b);
- Human Health Toxicity Values in Superfund Risk Assessments, OSWER Directive 9285.8-53 (USEPA, 2003a);
- RAGS: Volume I. Human Health Evaluation Manual. Part E, Supplemental Guidance for Dermal Risk Assessment (USEPA, 2004a);
- Guidelines for Carcinogen Risk Assessment (USEPA, 2005b);
- Supplemental Guidance for Assessing Susceptibility from Early-Life Exposure to Carcinogens (USEPA, 2005c):
- Exposure Factors Handbook (USEPA, 2011);
- Tier 3 Toxicity Value White Paper (USEPA, 2013)
- RAGS, Human Health Evaluation Manual Supplemental Guidance: Update of Standard Default Exposure Factors (USEPA, 2014a)
- ProUCL Version 5.1, Statistical Software for Environmental Applications for Data Sets with and without Nondetect Observations (USEPA, 2016);
- Regional Screening Levels (USEPA, 2018a).

The BHHRA evaluated potential human health effects using the following four-step paradigm, as identified by the USEPA (USEPA, 1989a):

- Data Evaluation and Hazard Identification
- Toxicity (dose-response) Assessment
- Exposure Assessment
- Risk Characterization

The BHHRA is organized into the following sections:

- Section 2 – Site Characterization and Conceptual Site Model
- Section 3 – Data Evaluation and Hazard Identification
- Section 4 – Dose-Response Assessment
- Section 5 – Exposure Assessment
- Section 6 – Risk Characterization
- Section 7 – Uncertainty Analysis
- Section 8 – Summary and Conclusions
- Section 9 – References

Tables and figures are presented at the end of the text. Note that tables are numbered based on the section in which they are referenced. Informational tables embedded within the text of the BHHRA are not numbered.

2 Site Characterization and Conceptual Site Model

A description of the Study Area and its setting is provided below, followed by a discussion of the human health CSM. The CSM describes potential sources, migration routes, routes of exposure, and potential receptors based on available information. The receptor/exposure pathway scenarios that are potentially complete and require further evaluation are identified. The CSM presented in this BHHRA report updates the preliminary CSM presented in the RI/FS Work Plan (AECOM, 2012).

2.1 Study Area Description

As discussed previously, the Study Area is divided into Landside and Waterside (Anacostia River) Investigation Areas, which are described below. The general Study Area location is shown on **Figure 1-1**. The Site, as defined by the property boundary on **Figure 1-2**, is located on the east side of the Anacostia River approximately 4.7 miles upstream of the confluence of the Anacostia and Potomac Rivers.

2.1.1 Landside Investigation Area

The Site has two distinct operational areas: a former power plant area to the west and the Benning Service Center to the east (see **Figure 1-2**). The Benning Service Center supports activities related to construction, operation, and maintenance of Pepco's electric power transmission and distribution system serving the Washington, DC, area. The Service Center occupies the largest part of the property (about 78%), and accommodates approximately 700 Pepco employees. Service Center employees work in maintenance and construction of Pepco's electric distribution system; system engineering; vehicle fleet maintenance and refueling; and central warehouses for all the materials, supplies, and equipment needed to operate the Pepco electrical distribution system. The Service Center also houses three electrical substations supporting Pepco's transmission and distribution system. The Benning Road Power Plant was constructed in 1906. Over the years, the power plant operated and subsequently retired several different generating units, reflecting the advances in technology and operating on different types of fuels. The power plant was shut down in 2012. Demolition and removal of the power plant building and related infrastructure commenced in 2014, and all demolition and site restoration activities were completed in May 2015. The Site will continue to be used as a Pepco Service Center.

The Site is completely surrounded by a fence with two guarded entrances, as indicated in **Figure 1-2**. The guard stations are manned 24 hours a day, 7 days a week. The majority of the Site is covered by impervious material such as concrete or asphalt. Storage areas not covered by impervious material are covered in gravel. Railroad tracks enter the Site from the south and run to the north. The tracks were formerly used to transport coal to the power plant and are no longer active.

As shown in **Figure 2-1**, land uses in the vicinity of the 77-acre Site include a mix of commercial, residential, parkland/green space, and transportation. The Site is bordered by a DC solid waste transfer station to the north, Kenilworth Maintenance Yard, owned by the National Park Service (NPS) to the northwest, the Anacostia River to the west, Benning Road to the south, and residential areas to the east and south (across Benning Road). Major transportation corridors in the area include the Anacostia Freeway running north-south and East Capitol Street NE running east-west. The Minnesota Avenue Metrorail Station of the Washington Metropolitan Area Transit Authority light rail system is located immediately to the east of the Site.

Aquifers underneath the Site consist of saturated sand layers within the Patapsco and Patuxent Formation and include (from shallowest to deepest) the Upper Patapsco Aquifer, the Lower Patapsco Aquifer, the Upper Patuxent Aquifer, and the Lower Patuxent Aquifer. The Lower Patapsco and upper Patuxent Aquifers are separated by the thick Arundel Clay unit. The Arundel Clay has very low conductivity and acts as a regional aquitard between the Patapsco and Patuxent Formations. The subsurface investigation identified a silt-clay semi-confining layer underlying much of the Site and dividing the Patapsco Formation aquifer into an upper water-bearing zone (UWZ) and lower water-bearing zone (LWZ). The top of the silt-clay layer was encountered between 25 and 40 feet below ground surface (bgs), and the layer averaged about 6 feet in thickness.

The Site is in Ward 7 in the District of Columbia, within the 20019 zip code. Ward 7 contains a mix of residences and parkland, including Fort Mahan Park, Fort Davis Park, Fort Chaplin Park, Fort Dupont Park, Kenilworth Park and Aquatic Gardens, Watts Branch Park, Anacostia River Park, and Kingman and Heritage Islands Park. The neighborhoods to the south of the Site along the east side of the River include River Terrace, Mayfair, and Eastland Gardens. Four schools are located within a 0.25-mile radius of the Site boundary: Thomas Elementary School, Cesar Chavez Middle and High School, Benning Elementary School, and River Terrace Elementary School (Google Earth). Drinking water in the area is provided by a remote municipal source (DC Water) that originates on the upper Potomac River.

2.1.2 Waterside Investigation Area

The Anacostia River begins in Bladensburg, MD, at the confluence of its two major tributaries, the Northwest Branch and the Northeast Branch, and flows a distance of approximately 8.4 miles before discharging into the Potomac River in Washington, DC (Sullivan and Brown, 1988). The upstream portion of the River is non-tidal. Below the confluence of the Northeast and Northwest Branches, the Anacostia is a tidal river with habitat suitable for a variety of freshwater and estuarine species, including American eel, brown bullhead, channel catfish, largemouth and smallmouth bass, carp, and sunfish. A water body-specific fish consumption advisory is in effect for the Anacostia and Potomac Rivers recommending against consumption of some species (catfish, carp, and American eel) and limited consumption of other species (e.g., largemouth bass, sunfish) (DOEE, 2016a). However, some people may not be aware of the advisory, or may choose to catch and eat river fish despite the presence of the advisory.

The public may access the River at several locations, including parks, boat docks, and launches. Anacostia Park, a 1,200-acre unit of National Capital Parks – East, stretches 5 miles along the banks of the Anacostia River between the Fredrick Douglas Memorial Bridge and the DC-Maryland line. Within the park, the Anacostia Riverwalk Trail runs along the shorelines of the River continuing beyond the north and south boundaries of the park. A public boat launch is located about 1.5 miles downstream from the Waterside Investigation Area. Dense vegetation along the east bank adjacent to the Site may limit access to the River in this area. The Langston Golf Course is located directly across the River from the Site. Kingman Island divides the main channel of the River from Kingman Lake to the west and provides recreation opportunities via pier and trail access. Based on the bathymetric survey conducted by Gahagan & Bryant Associates, Inc. for the RI in 2013, water depths in the Waterside Investigation Area range from approximately 4 to 14 feet below mean lower low water level in the channel and shallower toward the banks (see Section 3 of the RI Report). The average variation in the River's stage over a tidal cycle is approximately 3 feet.

Because of its location in the Washington metropolitan area, the majority of the watershed is highly urbanized. The Anacostia River has been the subject of numerous environmental studies, and was identified by USEPA, the Syracuse Research Corporation (SRC), and the National Oceanic and Atmospheric Administration (NOAA) as one of the most contaminated rivers in the Chesapeake Bay watershed (SRC and NOAA, 2000). The Site is one of six sites that have been identified by USEPA as potential sources of sediment contamination in the River (Fritz and Weiss, 2009).

Section 305(b) of the Federal Clean Water Act requires each state/district to monitor, assess, and report on the quality of its waters relative to designated uses established in accordance with the District's Water Quality Standards. Section 303(d) of the Act requires each state/district to list waters not meeting water quality standards and prioritize those waters for management. Reporting for these waters is submitted to USEPA every 2 years. According to the 2016 District of Columbia integrated water quality assessment report, the Anacostia River is on the District's 303(d) list of impaired waters. The impaired designated uses include fish consumption, as well as habitat for fish, other aquatic life, and wildlife due to nutrient/eutrophication biological indicators and chemical pollutants (DOEE, 2016b).

2.2 Human Health Conceptual Site Model

The human health CSM provides the framework for the human health risk assessment and is used to identify appropriate exposure pathways and receptors for evaluation in the risk assessment. The purpose of the CSM is to identify (1) potential source areas, (2) potential migration pathways of chemicals from source areas to environmental media where exposure can occur, (3) potential human receptors, and (4) potential exposure pathways by which chemical uptake into the body may occur. Potentially complete exposure pathways are identified for consideration for further evaluation in the risk assessment. For an exposure pathway to be complete, the following conditions must exist (USEPA, 1989a):

1. A source and mechanism of chemical release to the environment;
2. An environmental transport medium (e.g., air, water, soil);
3. A point of potential receptor contact with the medium; and
4. A human exposure route at the contact point (e.g., inhalation, ingestion, dermal contact).

The first step in developing the CSM is the characterization of the site setting and surrounding area. This includes characterization of current and reasonably foreseeable future land uses and potential receptors (e.g., residential, recreational, commercial/industrial). Potential exposure scenarios identifying appropriate environmental media and exposure pathways for current and reasonably foreseeable future land uses and receptors are then developed. Chemicals of Potential Concern (COPCs) are identified for each exposure pathway based on the application of risk-based screening criteria and other evaluation of the field sampling data. Each potentially complete exposure pathway for any COPC is evaluated quantitatively in the risk assessment. The CSM is meant to be a "living" model that can be updated and modified as appropriate when additional data become available.

Some receptor populations may be potentially exposed to COPCs by more than one pathway. Although there may be more than one potential exposure pathway, USEPA guidance (USEPA, 1989a) cautions that the first step is to identify reasonable exposure pathway combinations, and then to determine "whether it is likely that the same individuals would consistently face the reasonable maximum exposure by more than one pathway" [emphasis in the original]. With this in mind, the CSM is developed by constructing potential exposure scenarios and identifying the hypothetical receptors to be used in evaluating these exposures. It is important to note that the exposure scenarios are typically constructed for hypothetical receptors who are assumed to be the most frequently exposed. The receptors are not intended to represent specific individuals.

An updated preliminary human health CSM based on available data was presented in the Risk Assessment Work Plan Addendum (AECOM, 2016d). The preliminary CSM identified potential sources of

COPCs, including spills and releases, surface runoff, groundwater migration, storm sewers and outfalls, and atmospheric deposition. These sources may have resulted in impacts to environmental media, including soil, groundwater, sediment, and surface water in the River. Because of the presence of bioaccumulative chemicals, including polychlorinated biphenyls (PCBs), potential uptake into the food chain and bioaccumulation in biota including sport fish may also have occurred. Human receptor populations may subsequently contact COPCs present in these environmental media via direct contact (i.e., incidental ingestion and dermal contact) with fringe surface sediment[1] and surface water, and via indirect exposure, specifically consumption of fish tissue. **Figures 2-2** (On-Site Sources) and **2-3** (Off-Site Sources) present an updated human health CSM for the Study Area.

2.2.1 Landside Investigation Area

For the Landside Investigation Area, all direct human exposure pathways under the current scenario are judged to be incomplete or insignificant, based on both limited access and soil cover. There is tight security at the Site that limits the potential for access. The majority of the Site is covered by impervious material such as concrete or asphalt as shown on Figure 1-7 of the RI. Active storage areas not covered by impervious material are covered in gravel. Consequently, there is very little potential for individuals to trespass onto the Site and come into contact with impacted surface soils. The presence of impervious or gravel cover also limits the potential for on-Site workers to come into contact with surface soils. The facility's health and safety plan includes an employee hazard communication program and procedures that prevent or manage potential exposure to impacted subsurface soils by workers who may perform excavation activities on Site. Based on current and anticipated future Site conditions and uses, the Risk Assessment Work Plan concluded that direct current and future contact exposure pathways for on-Site soils are incomplete or insignificant (AECOM, 2012). The existing operational and institutional controls that are in place at the Site continue to provide effective exposure prevention measures. However, if any of these conditions were to change in the future, on-Site workers may potentially contact surface soil, and construction workers may contact subsurface soil via incidental ingestion, dermal contact, and inhalation of volatiles or dust derived from soil. Therefore, the Risk Assessment Work Plan Addendum (AECOM, 2016d) specified that the revised BHHRA would include an evaluation of potential future worker exposures to soil.

In the future, if Site access or security was to change and the existing soil cover removed, it is possible that recreational receptors would contact on-Site surface soil. Therefore, a future recreational user is

[1] Fringe surface sediment is sediment under water depths of a few feet or less. The surface sediment data set for the BHHRA was limited to these locations because of the greater potential for contact.

evaluated. It is assumed that future recreational exposures will be limited to the western portion of the Site next to Anacostia Avenue[2] (see **Figure 1-2**). This area was previously the location of the former power plant demolished between 2012 and 2015. This area of the Site remains under controlled access and Pepco has no plans to convert this area to public recreational use. Nonetheless, because this portion of the Site is the closest to the Anacostia River and the existing NPS park land located across Anacostia Avenue, DOEE directed that the BHHRA evaluate a hypothetical future exposure scenario in which this area becomes public park land or green space. The BHHRA otherwise assumes that the Site will remain industrial/commercial with secure fencing and 24-hour security to deter trespassing and will continue to be used as a service center into the foreseeable future due to the important role it serves in Pepco's electric transmission and distribution system. The available data do not suggest that historic operations have resulted in impacts to off-Site soils in residential areas. Therefore, on- and off-Site residential exposure scenarios are not evaluated.

Site groundwater is not used as a source of drinking water; thus, consumption of groundwater is not a complete exposure pathway. The depth to groundwater (UWZ) generally ranges from 9 to 16 feet bgs across the Site, with depths up to 26 feet bgs in the south-central portion of the Site (see Section 3 of the RI Report). While groundwater may be encountered if excavation depths reach an excess of 9 feet bgs, most underground utilities and other subsurface infrastructure at the Site that may require future maintenance, repair, or replacement are located at depths well above 9 feet bgs. Electric utility lines at the Site range from 3 to 8 feet bgs, which is above the shallowest depth of the UWZ. Therefore, no contact with groundwater is expected during maintenance of electric utility lines. The Metro and sewer lines are located deeper below ground surface. According to Pepco Underground, any maintenance on these lines would be performed from the inside by a designated confined-space-permitted contractor outfitted with appropriate personal protective equipment. Therefore, it is not anticipated that excavation below the water table for the purposes of utility maintenance will take place in the future. Additionally, based on experience, worker exposure to contaminated groundwater under a short-term excavation scenario typically poses minimal risk. Thus, direct contact with groundwater is considered to be an incomplete or insignificant potential exposure pathway and does not warrant further consideration in the BHHRA.

Vapor intrusion from groundwater into an excavation trench may occur; however, this potential route of exposure is anticipated to be of short duration, and any volatiles in trench air would be subject to

[2] The Risk Assessment Work Plan Addendum (AECOM, 2016d) also stated that recreational use of the off-Site parcel of land owned by the National Park Service (Kenilworth Maintenance Yard) would be evaluated. However, as discussed in Section 3.1.2, this area does not warrant further evaluation in the BHHRA.

windblown dispersion. Despite the short duration of the potential exposure, the potential for vapor intrusion from the UWZ into a future excavation trench was evaluated in this revised BHHRA.

Under the current use scenario, vapor intrusion into the indoor air of buildings is an incomplete exposure pathway, as there are no buildings in areas of elevated volatile organic compounds (VOCs) in groundwater. However, a screening level evaluation of the potential for vapor intrusion under a future scenario in which buildings are constructed in areas of elevated VOCs in groundwater was included in this revised BHHRA based on the results of additional groundwater sampling conducted during Phase II sampling activities.

Based on local hydrogeology and topography, Site groundwater may discharge to the Anacostia River. Therefore, the revised BHHRA includes an evaluation of the potential impacts of Site groundwater on River water and associated receptors.

The potential receptors and potentially complete exposure pathways evaluated in this BHHRA for the Landside Investigation Area are as follows:

- Current/Future Construction Worker. Potential direct contact (ingestion and dermal) with surface and subsurface soil and potential inhalation of soil-derived fugitive dust during utility or other construction work requiring excavation. In addition, the construction worker may be exposed to volatiles in the air of an excavation trench due to volatilization from groundwater infiltrating the trench.
- Future Outdoor Industrial Worker. Potential direct contact (ingestion and dermal) with surface soil and potential inhalation of surface soil-derived fugitive dust, in the event of a change in the existing Site use controls and existing on-Site soil cover in the future.
- Future Indoor Industrial Worker. Potential inhalation of volatile compounds in indoor air resulting from groundwater vapor intrusion.
- Future Recreational Visitors. Potential direct contact (ingestion and dermal) with surface soil, and potential inhalation of surface soil-derived fugitive dust in the western portion of the Site next to Anacostia Avenue (see **Figure 1-2**), if the area were to become publicly accessible in the future.

2.2.2 Waterside Investigation Area

For the Waterside Investigation Area, a number of potential human exposure pathways are potentially complete. Potential receptors include shoreline workers, anglers, and other receptors who visit the River to recreate (e.g., swimmers, waders, boaters). The potential Waterside Investigation Area receptors and how they may contact COPCs are described below and summarized in **Figure 2-2**. The potential receptors and potentially complete exposure pathways evaluated in this revised BHHRA are as follows:

- Current/Future Recreational Anglers. Potential direct contact with fringe surface sediment and surface water while fishing, and ingestion of fish from the Waterside Investigation Area.
- Current/Future Swimmers. Potential direct contact with fringe surface sediment and surface water while swimming in the Waterside Investigation Area.
- Current/Future Waders. Potential direct contact with fringe surface sediment and surface water while wading in the Waterside Investigation Area.
- Shoreline Workers. Potential direct contact with fringe surface sediment and surface water while performing maintenance, landscaping, or other activities along the shoreline of the River adjacent to the Site.

In addition, a current/future high-end consuming Angler scenario (i.e., potential direct contact with fringe surface sediment and surface water while fishing, and consumption of fish from the Waterside Investigation Area at a higher rate than recreational anglers) is evaluated in Section 7.3.2.2 of the uncertainty analysis.

2.3 Consideration of Background Conditions

The Anacostia River has been impacted by a variety of historical and ongoing sources of chemical, physical, and biological stressors from point and non-point sources, including National Pollutant Discharge Elimination System discharges, surface runoff, combined sewer and storm sewer outfalls, refuse disposal practices, tributary inputs, and atmospheric deposition (SRC and NOAA, 2000). The multitude of sources has resulted in diffuse distributions of some constituents, including polycyclic aromatic hydrocarbons (PAHs), metals, PCBs, and pesticides, with some localized hot spots (Wade et al., 1994; Velinsky et al., 1996; Velinsky et al., 2011). Surficial sediment concentrations have decreased over the past few decades, likely due to improved environmental practices, PCB use restrictions, and deposition of cleaner sediment (Velinsky et al., 2011). Based on fish tissue monitoring, concentrations of PCBs in tissue have also declined over the years (Pinkney, 2017[3]), although levels reflected by the most recent fillet sampling data from 2013 are still sufficiently elevated throughout the Anacostia and Potomac Rivers to warrant issuance of advisories warning against consumption of some species of fish (DOEE, 2016a, MDE, 2018).

The risk calculations presented in the BHHRA reflect total constituent concentrations, whether related to past Site activities or attributable to some other source. However, for purposes of evaluating responses to potential risks, it is essential to consider background information. USEPA's guidance on the role of background in the Superfund cleanup process (USEPA, 2002e) notes that a primary objective of

[3] Report was originally published in September 2014 and revised in November 2017.

CERCLA risk assessments is to provide information on risks that can be effectively addressed through remedial actions. Taking into account background area information during the risk assessment process provides a basis for distinguishing risks associated with site releases from risks resulting from the presence of constituents that may have migrated into the site, or that may reflect regional conditions related to human activities (Judd et al., 2003).

USEPA (2002d) defines background as: "Substances or locations that are not influenced by the releases from a site and are usually described as naturally occurring or anthropogenic: (1) Naturally occurring substances are present in the environment in forms that have not been influenced by human activity; (2) Anthropogenic substances are natural and human-made substances present in the environment as a result of human activities (not specifically related to the CERCLA site in question)." It further defines a background reference area as: "The area where background samples are collected for comparison with samples collected on site. The reference area should have the same physical, chemical, geological, and biological characteristics as the site being investigated, but has not been affected by activities on the site."

USEPA (2002e) provides the following guidance on addressing background in the risk assessment:

> *Specifically, the COPCs with high background concentrations should be discussed in the risk characterization, and if data are available, the contribution of background to site concentrations should be distinguished. COPCs that have both release-related and background-related sources should be included in the risk assessment.*

Therefore, consistent with USEPA guidance (2002e), the potential contribution from background has been evaluated in this BHHRA using data representative of background conditions. Appendix W of the RI Report provides the background evaluation, including the derivation of background threshold values (BTVs) and comparison with Study Area data.

3 Data Evaluation and Hazard Identification

The purpose of the hazard identification process is two-fold: (1) to evaluate the nature and extent of chemicals present in site media; and (2) to identify COPCs for further quantitative evaluation in the risk assessment. This step involves compiling and summarizing the data relevant to the risk assessment and selecting COPCs based on a series of screening steps. Section 3.1 describes the data sets that were used, including the assessment of data quality. Section 3.2 describes the hazard identification process, including the calculation of summary statistics and the COPC screening process.

3.1 Data Sets Used in BHHRA

As discussed in detail in Section 2 of the RI Report, analytical chemistry data collected between 2013 and 2018 comprise the soil, groundwater, sediment, and surface water data sets for the BHHRA. Details regarding the sampling and analysis program are found in the RI/FS Work Plan (AECOM, 2012), three addenda to the RI/FS Work Plan (AECOM, 2014a, AECOM, 2014b, AECOM, 2016e), and the RI Report and associated appendices. The fish tissue data were obtained from publicly available sources, including DOEE and United States Fish and Wildlife Service (USFWS) fish sampling programs. The data sets utilized in the BHHRA are summarized below for the Landside and Waterside evaluations. In addition, the data sets for the Anacostia Park Property adjacent to Kenilworth Maintenance Yard and background are summarized.

3.1.1 Landside Investigation Area Data

Soil and groundwater sampling were conducted over two phases, which are described in detail in the RI Report, Section 2.1 (Phase I) and Section 2.3 (Phase II). PCBs were analyzed as both congeners and Aroclors, although the vast majority of samples were analyzed as Aroclors. The FS will include details on the congener analysis, which was conducted on a limited subset of samples for forensic purposes. The data sets are summarized below. The Aroclor data were used in the evaluation of abiotic media in this BHHRA.

Soil

Soil sampling was conducted between February 2013 and July 2018, and consisted of surface and subsurface soil samples. As discussed in greater detail in Section 2 of the RI Report, depending on the characterization and delineation objectives, soil samples were submitted for chemical analysis, including inorganics, PCBs, pesticides, total petroleum hydrocarbon (TPH) fractions, semivolatile organic compounds (SVOCs), and dioxins and furans. Not all chemicals were analyzed in each sample. Surface soil is defined as the ground surface to a depth of 1 foot bgs. However, several samples were collected from beneath obstructions such as concrete or asphalt, and the ground surface was considered the top of the slab. The first sample collected below the slab is therefore considered surface soil. Because subsurface excavations typically do not exceed 10 to 15 feet bgs, only subsurface soil data from samples collected to a maximum depth of 16 feet bgs were included in the BHHRA. The soil sample locations are depicted in **Figure 3-1**, and samples included in this BHHRA are listed in **Table 3-1**. The soil sample results are presented in Section 4 of the RI Report.

Groundwater

Groundwater samples were collected using Direct-Push Technology (DPT) at locations across the Site between March 2013 and March 2017. These samples were collected to characterize various target areas across the Site, and the chemical analysis was dependent on the area being investigated.

A total of 30 monitoring wells were installed as nested well pairs at 15 locations across the Site. Two monitoring wells were installed at each location, a shallow well in the UWZ and a deep well in the LWZ. Two rounds of monitoring well sampling took place, the first in November 2014 and the second between November and December 2016. Samples were analyzed for metals, dioxins and furans, pesticides, PCBs, SVOCs, VOCs, and forensics parameters,[4] but not every sample was analyzed for the full list.

As previously noted, exposure pathways for on-Site groundwater are judged to be complete or potentially complete only for inhalation of vapors in an excavation trench, inhalation of the indoor air of a hypothetical future building, and groundwater migration to the Anacostia River. To evaluate the potential impact of groundwater on the River, groundwater data from the four monitoring wells located adjacent to the western downgradient boundary of the Site were used (MW-01, MW-02, MW-03, and MW-04), as well as MW-08 and MW-11, which are located along the northwestern and northern downgradient Site boundary. The groundwater data from these six locations have been identified as representative of the types and concentrations of chemicals that may be migrating from the Site into the Anacostia River. As discussed in the RI Report, contaminants detected in on-Site wells further from the River are not expected to contribute significantly to the potential migration to surface water pathway. Groundwater samples from both the UWZ and LWZ were used in the evaluation of groundwater migration to surface water.

The locations of the DPT borings and monitoring wells are depicted in **Figure 3-1**. Only groundwater samples from the UWZ were used in this BHHRA to evaluate the excavation trench and vapor intrusion

[4] The forensics evaluation will be provided in the FS.

pathways. Groundwater samples included in the BHHRA are listed on **Table 3-3**. The groundwater analytical results are presented in Section 4 of the RI Report.

3.1.2 Anacostia Park Property Adjacent to Kenilworth Maintenance Yard Data

Anacostia Park Property Soil

Records provided by NPS indicate that Pepco had proposed to stage dredge spoils on a portion of the Anacostia Park property during an intake dredging project in 1967. It is not known if the dredge spoil staging activity actually took place. At DOEE's direction, Pepco conducted a field investigation in the suspected dredge spoils area on the NPS property. The area proposed for staging is located to the west of the Site and adjacent to the Anacostia River, as shown on **Figure 3-2**. Sample locations are indicated on **Figures 3-2** and **3-3** and are listed on **Table 3-1**.

With the exception of arsenic and chromium, sample results (composite and discrete) were below screening levels. As indicated in the RI Report, arsenic was detected in all 12 discrete surface soil samples at concentrations ranging from 2.3 milligrams per kilogram (mg/kg) to 15 mg/kg. Total chromium was detected in all 12 samples at concentrations ranging from 26 mg/kg to 51 mg/kg, and hexavalent chromium was detected in three samples at concentrations less than 1 mg/kg. Based on the discrete sampling results, hexavalent chromium is below its screening level, and concentrations of trivalent chromium (total chromium minus hexavalent chromium) are below its screening level. Concentrations of arsenic in Anacostia Park property soils are below the arsenic BTV of 17 mg/kg derived in Appendix W of the RI Report.

Anacostia Park Property Groundwater

Three borings were advanced by DPT in April 2017. Groundwater samples were collected from the water table aquifer in each of the three borings. The samples were analyzed for inorganics, PCBs, pesticides, TPH fractions, SVOCs, VOCs, and dioxins and furans. The analytical results are presented in Section 4 of the RI Report. As discussed in greater detail in Section 4.5 of the RI Report, inorganic concentrations are close to or below background levels, indicating that they are likely naturally occurring.

Anacostia Park Property Summary

The soil and groundwater data from the Anacostia Park Property indicate that (1) there are no adverse impacts from the alleged historical staging of dredge spoils on Anacostia Park property, and (2) groundwater transport from the Site has not impacted the subsurface conditions at Anacostia Park. Therefore, soil and groundwater at the Anacostia Park property are not further evaluated in this BHHRA.

3.1.3 Background Data for Soil and Groundwater

Soil

To support the refined background evaluation for Site soil, background soil samples were collected from 20 locations in the vicinity of the Site. The background locations were selected away from known or suspected sources of contamination and are considered to be representative of urban background conditions within northeast Washington, DC. Background surface soil samples were collected from 0 to 1 feet bgs, and subsurface soil samples were collected from 3 to 4 feet bgs. Background samples were analyzed for inorganics, PCBs (Aroclors), pesticides, dioxins and furans, TPH, SVOCs, and VOCs. The background soil sample locations are depicted in **Figure 3-4**, and samples are listed in **Table 3-2**. The analytical results are presented in Appendix W of the RI Report.

Groundwater

To support the refined background evaluation for groundwater, groundwater samples were collected via DPT drilling and temporary well sampling methods at 10 background locations in the vicinity of the Site. Consistent with the background soil sample locations, the background groundwater sample locations were selected away from known or suspected sources of contamination and are considered to be representative of urban background conditions within northeast Washington, DC. Initial background groundwater sampling was conducted from March 2 to April 20, 2017, and additional locations were sampled from August 22 to 29, 2017. Background samples were analyzed for inorganics, PCBs (Aroclors), pesticides, dioxins and furans, TPH, SVOCs, and VOCs. Background groundwater sample locations are shown on **Figure 3-4**, and the samples are listed in **Table 3-4**. The analytical results are presented in Appendix W of the RI Report.

3.1.4 Waterside Investigation Area Data

3.1.4.1 Sediment

Sediment data are available from the Waterside Investigation Area and from background locations.

Waterside Investigation Area

Sediment sampling was conducted between November 2013 and June 2017. Surface sediment samples were collected from 0 to 4 or 6 inches below sediment surface (**Figure 3-5**). Subsurface sediment samples collected at depths greater than 6 inches were not included in the risk assessment, per the approved Risk Assessment Work Plans (AECOM, 2012, 2016d).

As depicted in **Figure 3-5**, surface sediment samples were collected throughout the Waterside Investigation Area. Transects of three samples spanning the River channel were located along the length of the Waterside Investigation Area. Some samples were collected from locations close to the shoreline adjacent to the Site; others were collected mid-channel and closer to the opposite shore and under deeper water. In general, water depths along the shoreline are shallower and channel slopes more gradual on the east side of the River adjacent to the Site. USEPA (2004a) provides the following guidance regarding sediment sample locations for a human health risk assessment:

> *Sediment samples must be located in areas in which individuals are likely to come into direct contact with the sediments. For wading and swimming, this includes areas which are near shore and in which sediments are exposed at some time during the year. Sediments which are consistently covered by considerable amounts of water are likely to wash off before the individual reaches the shore.*

Because of the greater potential for contact with surface sediment under water depths of a few feet or less, the surface sediment data set for the BHHRA was limited to these locations, referred to as fringe surface sediment locations. Fringe surface sediments were identified as locations falling within the low tide minus 1 foot area, consistent with the Draft RI Report for the Anacostia River Sediment Project (ARSP; TetraTech, 2018) and are shown on **Figure 3-5**. Additionally, only fringe surface sediment locations located on the east bank of the River were included, since these are the locations that represent potential exposures closest to the Site. The fringe surface sediment data collected by Pepco were supplemented with relevant fringe surface sediment data collected by DOEE for the ARSP. These data are reported in the ARSP RI Report (TetraTech, 2018).

Based on the combined data sets, a total of 42 fringe surface sediment samples from 32 locations were identified on the east bank (see **Table 3-5**). **Table 3-5** provides the rationale for excluding some locations from the BHHRA (either because the location is not located in a fringe area or because it is not along the east bank of the River). Of the 42 fringe surface sediment samples, all but one of the ARSP samples were analyzed for PCBs (Aroclors) and metals. A subset of fringe surface sediment samples was analyzed for VOCs (13 samples), SVOCs (33 samples), pesticides (28 samples), petroleum hydrocarbons (21 samples), and dioxins and furans (24 samples). Fringe surface sediment analytical results used in this BHHRA are presented in **Attachment A**.

<u>Background</u>

Pepco collected 11 background/upstream surface sediment samples and 4 duplicates (see **Table 3-6** and **Figure 3-6**). These were supplemented with 38 surface sediment samples/locations and 1 duplicate collected for the ARSP (TetraTech, 2018). The selection of the upstream Site-specific background locations is addressed in Technical Memorandum #2 which was approved by DOEE on October 14, 2016. As part of the background evaluation for this RI, Pepco performed a further analysis of potential tidal influence to confirm that all sediment sampling locations included in the Site-specific background dataset were upstream of any influence from the Site. The details of the analysis and the results are provided in Appendix W. Pepco's analysis confirms that the background location SEDBACK20 and background locations upstream of SEDBACK20 will not be influenced by any Site-related contaminants as a result of tidal exchanges. No sampling locations downstream of SEDBACK20 were included in the dataset for the purpose of calculating site-specific background values.

Based on the combined data sets, 49 background surface sediment samples and 5 duplicates were identified. The background surface sediment samples were analyzed for PCBs VOCs, SVOCs, pesticides, petroleum hydrocarbons, and dioxins and furans. The background surface sediment data set is presented in Appendix W of the RI Report.

3.1.4.2 Surface Water

DOEE collected samples of surface water in September and October 2013 at 20 locations in the Anacostia River (10 in the Waterside Investigation Area and 10 from background locations). These locations are depicted in **Figure 3-5** (Site-adjacent) and **Figure 3-6** (background). The surface water samples were collected from approximately 1 foot above the sediment-water interface. All 20 samples were analyzed for PCBs (Aroclors), total and dissolved metals, and PAHs. A subset of 11 samples (5 in the Waterside Investigation Area and 6 from background locations) was analyzed for VOCs, SVOCs, pesticides, and dioxins and furans. **Table 3-7** lists the surface water samples included in this BHHRA. The analytical results are presented in Section 4 of the RI Report.

While surface water samples were collected by DOEE for the ARSP, only three of the sample locations (R5-05, R5-06, and R6-17[5]) are within the Waterside Investigation Area. Location R5-05 was sampled once in October 2014; sampling methods were similar to those used by Pepco. Locations R6-06 and R6-17 were sampled four times in 2016 under maximum (spring/summer) and minimum (fall/winter) river flow conditions. As the Pepco data have better spatial coverage than the DOEE data, and the collection methods for the DOEE 2016 data are dissimilar, only the Pepco data were included. The uncertainty associated with this is discussed in Section 7.

[5] The surface water sample from location R6-17 was collected from within the Pepco Waterside Investigation Area. The sediment and pore water samples were collected upstream of Pepco and are therefore included in the background data set.

3.1.4.3 Fish Tissue Data

As agreed with DOEE, samples of fish tissue were not collected during this program (AECOM, 2012). Rather, as specified in the Risk Assessment Work Plan (AECOM, 2012), other studies conducted in the Anacostia River and the Potomac River were evaluated to determine whether relevant and appropriate fish tissue data are available.

Several investigations of fish tissue chemistry have been conducted for the Anacostia and Potomac Rivers, including data summarized by Velinsky and Cummins (1996), SRC and NOAA (2000), Haywood and Buchanan (2007), Pinkney et al. (2001), and Pinkney (2009, 2017). Two sources of recent fish tissue data were identified: (1) sampling conducted in 2013 by USFWS in the District's stretch of the Anacostia and Potomac Rivers and reported in Pinkney (2017), and (2) sampling conducted by TetraTech in 2016 in the upstream non-tidal portion of the Anacostia River above the DC-Maryland state line and the northeast and northwest tributaries (TetraTech, 2018). The tissue sampling areas for each program are presented in **Figure 3-7** (Anacostia), **Figure 3-8** (Potomac), and **Figure 3-9** (Upstream Non-Tidal Anacostia), and discussed below.

The available fish tissue data were evaluated according to the following five river reaches:

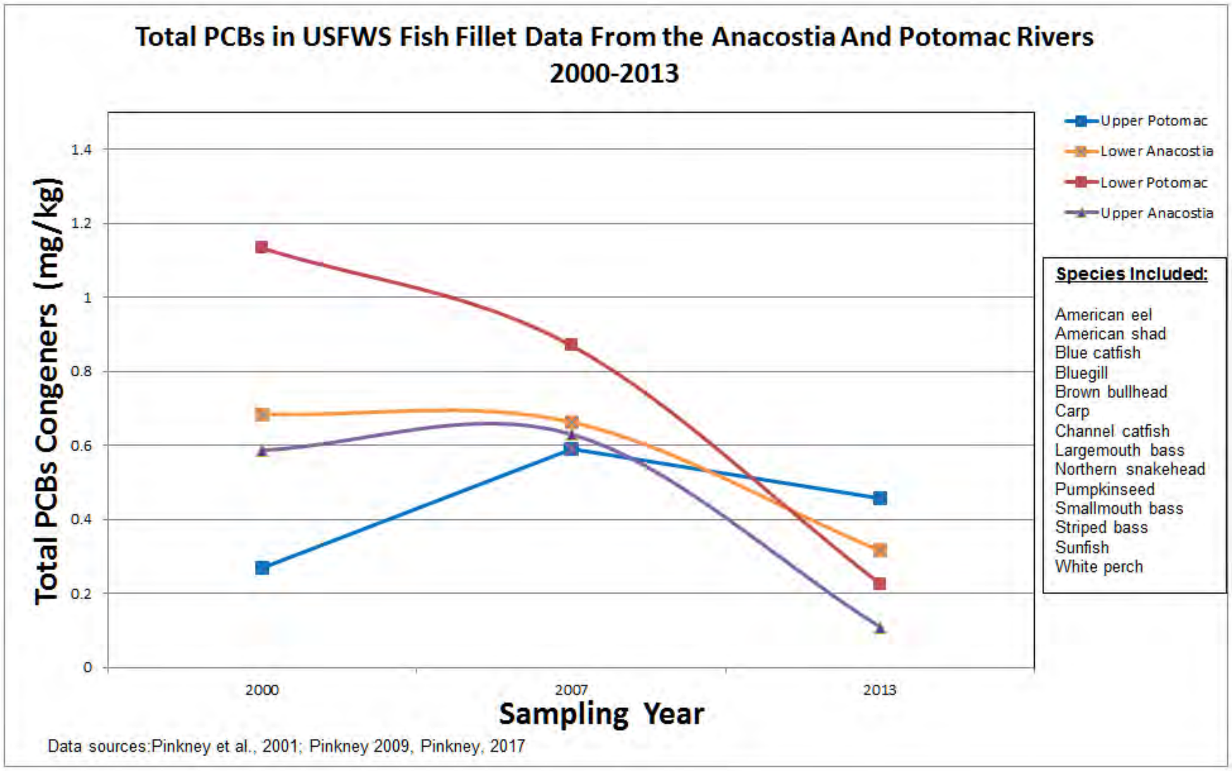
- Upper Anacostia River Area (upstream of the CSX bridge); this is an approximately 3.2 mile reach, encompassing the Waterside Investigation Area (see **Figure 3-7**), and extending approximately 1.3 miles downstream and 1.9 miles upstream of the Benning Road bridge;
- Lower Anacostia River Area (downstream of the CSX bridge);
- Lower Potomac River (downstream of the 14th Street bridge);
- Upper Potomac River (upstream of the 14th Street bridge);
- Upstream Non-Tidal Anacostia River (north of the Maryland state line); this is upstream of the Waterside Investigation Area and was used as the background area.

The four reaches comprising the Upper and Lower Anacostia and Upper and Lower Potomac Rivers were defined in the fish tissue sampling conducted in 2013 by USFWS (Pinkney, 2017). Composite fish fillet samples from each of these four reaches were collected in support of the District's fish consumption advisories, not as part of an RI program (Pepco Benning, ARSP, or other), and therefore were not intended to assign attribution to any upland source (note: these data were also used in DOEE's ARSP).

Because the exact collection points are not specified in the Pinkney study, the samples collected in the Upper Anacostia River are assumed to reflect overall conditions within the several-mile-long river reach that was sampled (or possibly the larger home range for some of the fish species sampled) and may not reflect the specific conditions within the Waterside Investigation Area. The same qualification applies for the fish samples collected within the Lower Anacostia and the Potomac River. Accordingly, although the tissue data for the Upper Anacostia Reach were used for this BHHRA per the direction of DOEE, there is insufficient information to make any definitive conclusions about the relationship between this fish tissue data and specific conditions within the Waterside Investigation Area. This will be discussed further as part of the uncertainty analysis.

U.S. Fish and Wildlife Tissue Data

Pinkney (2017) reported on the collection of fish tissue samples in 2013 by USFWS and DOEE in the Upper and Lower Anacostia River and Upper and Lower Potomac River sampling areas to support DOEE's fish consumption advisories. USFWS and DOEE also conducted tissue sampling in these areas in 2000 (Pinkney et al., 2001) and 2007 (Pinkney, 2017). A substantial decline in median PCB tissue concentrations was observed in all species except sunfish (Pinkney, 2017). The figure below shows tissue concentrations over time for the USFWS fillet data (all species combined) for sampling years 2000, 2007, and 2013. As shown below, concentrations in all reaches declined between 2000 and 2013. The decline does not appear to be related to differences in fish size or lipid content, as Pinkney (2017) noted that similar-sized fish were collected over the years and there was no discernable pattern in lipid content among species over time.



The 2013 USFWS tissue data were selected for evaluation in the BHHRA because these data are the most recent available, and the Upper Anacostia sampling reach includes the Waterside Investigation Area. The 2013 USFWS tissue data for the Upper and Lower Potomac and for the Lower Anacostia were also evaluated in the BHHRA to provide information regarding potential risks from fish consumption in the larger regional area. **Table 3-8** summarizes the species collected from each area.

All specimens were filleted, and the skin was left on for most species with the exception of channel and blue catfish (skin-off fillets) and American eel (skin and viscera removed, and muscle and bone included in the sample). The fillet is the principal part of the fish typically consumed by anglers, and therefore is the tissue type of greatest interest for risk assessment (USEPA, 2000; Gibson and McClafferty, 2005). Chemical analyses of the USFWS data included PCB congeners, PAHs, pesticides, polybrominated diphenyl ethers, metals, lipids, and moisture content. PCB congener analysis included a list of 119 congeners, including the 12 congeners with presumed dioxin-like effects (USEPA, 2010).

The fish tissue data were validated as part of the RI for the ARSP (TetraTech, 2018). Qualifiers were added to the data in some cases, and where the laboratory reported results below the method detection limit, results were raised to the reporting limit and qualified as not detected (U). Results between the detection limit and reporting limit were qualified as estimated (J). Therefore, in some cases, the validated data used in this BHHRA will differ from that presented in Pinkney (2017). The validated results for the Anacostia fish fillet samples were presented in Appendix A of the ARSP RI Report (TetraTech, 2018). The analytical results used in this BHHRA are presented in **Attachment A.**[6]

DOEE Fish Tissue Data

Fish tissue samples were collected from the Upstream Non-Tidal Anacostia River in 2016 and were reported in the ARSP RI Report (TetraTech, 2018). A total of 29 fish fillet samples were collected and analyzed for dioxins and furans, PCBs, pesticides, metals, and SVOCs. Of the 29 samples, 19 were largemouth bass, six were smallmouth bass, three were striped bass, and one was a northern snakehead. The samples are listed in **Table 3-8**. The results are presented in **Attachment A**.

3.1.5 Data Quality Assessment

The data collected by AECOM as part of the RI program for the Study Area were validated by project chemists as specified in the Quality Assurance Project Plan (QAPP) (AECOM, 2012). All project data from laboratory chemical analyses were validated using criteria specified in the approved QAPP, the relevant USEPA reference methods, and USEPA's National Functional Guidelines for Inorganic and Organic Data Review (USEPA, 2008). Note that the data quality assessment performed as part of the Benning Road RI did not include the tissue data collected by other parties. TetraTech conducted Phase 2B validation of the fish tissue data sets collected by DOEE (Pinkney, 2017, TetraTech, 2018). Pinkney (2017) noted that quality assurance procedures followed included the analysis of blanks, laboratory and field replicates, and standard reference materials.

The laboratory Quality Control (QC) results for the RI samples, specified as laboratory deliverables in the QAPP, were reviewed. The method-specific QC results included method blanks, equipment blanks, laboratory control samples, matrix spikes, matrix duplicates, laboratory duplicates, field duplicates, and/or surrogates, and were summarized on QC forms, where applicable. Additional method-specific parameters and the laboratory report narratives, which detail all QC non-conformances, were also reviewed with regard to any potential impacts to the sample data usability.

Qualifiers were applied to the data due to QC non-conformances where applicable. Upon completion of the data validation of each data set, data validation reports, which summarize the sample delivery group(s) and parameter(s) reviewed, and any QC non-conformances, were prepared. In addition, the

[6]The RI Report (TetraTech, 2018) did not include all of the analytes reported in Pinkney (2017). Therefore, for those analytes, the data were taken directly from Pinkney (2017). Additionally, some of the data for two carp samples (UACA01 and LPCA01) were transposed in the 2014 Pinkney publication and were corrected based on the 2017 revised publication.

reports summarize the qualifiers applied to the data as a result of any non-conformances noted during the validation process. Data validation reports for each data set are included in Appendix S of the RI Report. A summary of the data validation and project quality assurance assessments is provided in Section 4 of the RI Report. Overall, more than 99% of the data reviewed was found to be reliable and acceptable for use in risk assessment and remedial decision-making.

Analytical data were compiled and tabulated in a database for statistical analysis. **Tables 3-1** to **3-8** identify samples included in this BHHRA for the various media, as summarized below.

Area	Matrix	Number of Samples for BHHRA
Landside Investigation Area	On-Site Surface Soil (0-1 ft bgs)	291
	On-Site Subsurface Soil (1 to 16 ft bgs)	623
	On-Site Groundwater (UWZ)	125
	On-Site Downgradient Groundwater (LWZ and UWZ)	6 LWZ wells and 6 UWZ wells
Waterside Investigation Area	Anacostia River Fringe Surface Sediment	42
	Anacostia River Surface Water	10
	Upper Anacostia River Fish Tissue - Species include blue catfish, brown bullhead, channel catfish, carp, largemouth bass, northern pike, and sunfish	7
Background	Background Surface Soil (0-1 ft bgs)	19
	Background Subsurface Soil (3-4 ft bgs)	19
	Background Groundwater	14
	Anacostia River Surface Sediment (background)	49
	Anacostia River Surface Water (background)	10
	Upstream Non-Tidal Anacostia River Fish Tissue - Species include largemouth bass, striped bass, smallmouth bass, and northern snakehead	29
Regional	Lower Anacostia River Fish Tissue - Species include American eel, blue catfish, channel catfish, carp, largemouth bass, and sunfish	6
	Lower Potomac River Fish Tissue - Species include American eel, American shad, brown bullhead, blue catfish, carp, channel catfish, largemouth bass, and sunfish	9
	Upper Potomac River Fish Tissue - Species include American eel, brown bullhead, carp, channel catfish, largemouth bass, northern snakehead, striped bass, sunfish, and white perch.	9

3.2 Hazard Identification

Hazard identification is the first step in a four-step process of a BHHRA (USEPA, 1989a). As noted above, a major purpose of the hazard identification step is to identify a subset of COPCs from all chemicals detected during the investigation. These COPCs are then carried forward for quantitative evaluation in the subsequent baseline risk assessment.

The COPC screening process is intended to identify the following:

1. Chemicals that pose negligible risks and can be eliminated from further evaluation, and

2. Chemicals that merit further evaluation, either quantitatively or qualitatively, based on their potential to adversely affect humans depending on specific types of exposures.

This section describes the approach used to summarize the data and the steps followed to identify the human health COPCs. The results of the screening process are presented, and the COPCs retained in each medium for further evaluation in the BHHRA are summarized. Screening levels used in the COPC selection are described in Section 3.2.2 and are presented in **Tables 3-9** to **3-12**.

3.2.1 Summary Statistics

Summary statistics, consisting of frequency of detection, minimum and maximum detections, and arithmetic mean concentration, were calculated for detected chemicals in soil, groundwater, fringe surface sediment, surface water, and fish tissue, as shown in **Tables 3-13** to **3-21**.

When a sample and a duplicate pair were collected, they were treated as one sample for calculation of summary statistics (including maximum detection and frequency of detection). When a chemical was detected in both the sample and the duplicate, the higher concentration was used.[7] When chemicals were not detected in either the sample or its duplicate, the higher sample-specific quantitation limits was used. When a chemical in one of the pair was reported as not detected and the chemical was detected in the other, the detected concentration was used to represent the value. The following summary statistics are presented, reflecting the rules stated above regarding sample/duplicate pairs:

- Frequency of Detection: The frequency of detection is reported as a ratio based on the total number of samples analyzed and the number of samples reported as detected for a specific chemical.
- Maximum Detected Concentration: This is the maximum detected concentration for each chemical/area/medium combination.
- Mean Detected Concentration: This is the arithmetic mean concentration for each chemical/area/medium combination based on detected results only.
- Minimum Detected Concentration: This is the minimum detected concentration for each chemical/area/medium combination.

[7] In comments on the preliminary BHHRA, DOEE requested that sample/duplicate pairs be evaluated based on relative percent difference (RPD) between the parent and duplicate sample, using the average where the RPD is less than or equal to 25% and the maximum where the RPD is greater than 25%. To simplify, the maximum was conservatively used in this BHHRA.

Calculation of Totals

Total PCBs were calculated for each sample by summing the detected individual PCB Aroclor or congener results (fish tissue results only). If none of the individual PCB Aroclors/congeners were detected, the total concentration was flagged as non-detect (U-qualified) with a reporting limit equal to the maximum reporting limit of the individual PCB Aroclors/congeners in the total.

For samples with dioxin and furan results, the concentration of 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (2,3,7,8-TCDD) toxicity equivalence (TEQ) was calculated, as described in Section 4.6.1. If none of the dioxin and furan congeners were detected, the sample total was flagged as non-detect (U-qualified) and the 2,3,7,8-TCDD-TEQ concentration was set equal to the highest toxicity-weighted reporting limit.

PCB-TEQs for fish tissue were calculated for the 12 PCB congeners considered to have potential dioxin-like toxicity, as described in Section 4.6.2.2. The same method used to treat non-detected congeners in the calculation of 2,3,7,8-TCDD-TEQ concentrations was also used for PCB-TEQ.[8]

Chromium

Many metals can exist in different oxidation states; for some metals, the oxidation state can have different toxicities. This is the case for chromium. Chromium exists in two common oxidation states: trivalent chromium (chromium-3, Cr [III], or Cr+3), and hexavalent chromium (chromium-6, Cr [VI], or Cr+6). Trivalent chromium is essentially nontoxic as evidenced by its residential soil screening level of 120,000 mg/kg (USEPA, 2018a). It can be bought over-the-counter as a supplement and is included in most vitamins. Hexavalent chromium was concluded to be a human carcinogen by the inhalation route of exposure (USEPA, 2018b). Chromium is most commonly present in the environment in the trivalent state because typical conditions in the environment favor the reduction of chromium from the hexavalent to the trivalent state. Hexavalent chromium in soil is expected to be reduced to trivalent chromium by organic matter, which is facilitated by low pH (ATSDR, 2012). In addition, if hexavalent chromium is ingested, it is rapidly converted to the trivalent form after entering the stomach and is therefore not considered by USEPA to pose a cancer risk via the ingestion route of exposure (USEPA, 2018b).

Chromium (total) was detected in soil, groundwater, fringe surface sediment, surface water, and fish tissue. There is no history of using chromium at the Site, so it is likely that the form of chromium present

[8] PCB-TEQs for fish from the tidal Anacostia and Potomac Rivers presented in the ARSP RI Report (TetraTech, 2018) did not include PCB-156, which is identified by USEPA as a dioxin-like congener (USEPA, 2010). PCB-TEQs for this BHHRA were calculated to include PCB-156. Furthermore, where co-eluting congeners included dioxin-like and non-dioxin-like congeners, the toxicity equivalency factor (TEF) for the dioxin-like congener was used. This approach is conservative and results in a marginal increase in the PCB-TEQ result.

in soil is trivalent. To verify this assumption, soil samples were collected from the Landside Investigation Area, as well as the Anacostia Park property, and analyzed for both total chromium and hexavalent chromium. The data are presented in **Table 3-22.** The percent of hexavalent chromium was calculated for each sample. The average percent hexavalent chromium was calculated in several ways, both including and excluding non-detected results, and based on the combined Landside Investigation Area and Anacostia Park data sets. The calculated averages range from less than 1% to about 1.5%. Therefore, it is assumed that hexavalent chromium is present at 1.5% of total chromium in soil for the evaluation of samples for which speciation is not available. Given the lack of history of chromium use at the Site, and the low detections in soil, it is unlikely that hexavalent chromium is present in other media at the Study Area. Therefore, total chromium is evaluated as trivalent chromium in soil, groundwater, fringe surface sediment, surface water, and fish tissue.

Arsenic

Arsenic was reported as total arsenic in the fish tissue samples. The Federal Drug Administration (FDA, 1993) estimated that 10% of the total arsenic in fish tissue is the more toxic inorganic form. Others have reported that the inorganic form usually comprises only a small fraction of total arsenic in fish and shellfish (typically less than 10%) (Schoof et al. 1999, Greene and Crecelius 2006, Karouna-Renier et al. 2007), with the remainder consisting of less toxic organic forms (ATSDR, 2007). In the analysis of the Anacostia River and Potomac River fish tissue data, Pinkney (2017) considered total arsenic concentrations that were at least 10 times the inorganic arsenic guidance value as exceedances. Therefore, while COPC selection is based on the results for total arsenic, the derivation of fish tissue exposure point concentrations (EPCs) is based on the assumption that 10% of total arsenic is inorganic and 90% is organic.

3.2.2 Selection of COPCs

COPCs are a subset of the complete set of chemicals detected at a site that are carried through the quantitative risk assessment process. The selection of COPCs identifies those chemicals observed in site media that have the most potential to be a significant contributor to human health risk (USEPA 1993a, 1989a). As stated in USEPA guidance (USEPA, 1993a):

> *Most risk assessments are dominated by a few compounds and a few routes of exposure. Inclusion of all detected compounds at a site in the risk assessment has minimal influence on the total risk. Moreover, quantitative risk calculations using data from environmental media that may contain compounds present at concentrations too low to adversely affect public health have no effect on the*

overall risk estimate for the site. The use of a toxicity screen allows the risk assessment to focus on the compounds and media that may make significant contributions to overall risk.

Several factors are typically considered in identifying COPCs for risk assessment, including toxicity and magnitude of detected concentrations, frequency of detection, and essential nutrient status. Whether a chemical's presence is a result of site-related activities or is an artifact of natural and/or anthropogenic activities, background conditions may also be considered, although upfront elimination of COPCs based on consistency with background is generally not performed (USEPA, 2002e).

For this BHHRA, a toxicity screening approach was used to identify COPCs by comparing the maximum concentrations of chemicals detected in each medium to conservative risk-based screening levels (RBSLs).[9] RBSLs were selected in accordance with the Risk Assessment Work Plan and Addendum (AECOM, 2012, 2016d). In addition, essential nutrient status was considered; calcium, iron, potassium, and sodium were not identified as COPCs, as they are considered essential nutrients. The identification of appropriate RBSLs and the results of the COPC screening are discussed below on a medium-specific basis. For chemicals with RBSLs for both potential carcinogenic and noncarcinogenic effects, the lower of the two was used for screening. The selected RBSLs are presented in **Tables 3-9** to **3-12** for soil and fringe surface sediment, groundwater, surface water, and fish tissue, respectively.

3.2.2.1 Landside Investigation Area COPC Selection

<u>Soil</u>

The USEPA Regional Screening Levels (RSL) for industrial soil (USEPA, 2018a) were used to identify soil COPCs (see **Table 3-9**). The industrial soil RSLs are derived assuming daily year-round soil contact by an adult worker assuming incidental ingestion, dermal contact, and inhalation of soil-derived dusts and vapors for 25 years. The RSLs are based on a target risk of $1x10^{-6}$ for potential carcinogens and a target hazard quotient (HQ) of 1 for potential noncarcinogens (or a target HQ of 0.1 to account for potential additivity of chemicals with the same toxic endpoint) (USEPA, 1993a, 2018a). For screening of noncarcinogenic chemicals, the more conservative RSLs corresponding to an HQ of 0.1 were used. Use of these RSLs for screening occasional worker or recreational soil contact exposures is very conservative.

Table 3-13 presents the COPC screening results for on-Site soil. The maximum detected concentration of total chromium (400 mg/kg) is below the trivalent chromium industrial soil RSL (180,000 mg/kg). Assuming that hexavalent chromium may be present at 1.5% of total chromium (see Section 3.2.1), an

[9] The RBSL for lead is derived using the Adult Lead Model (USEPA, 2003b), which uses the average soil exposure concentration in the calculation of the fetal blood lead concentration of an adult female worker. For consistency with the recommended application of the model, the average lead concentration is used in COPC screening.

estimated maximum concentration of 6 mg/kg hexavalent chromium was calculated for the samples for which speciation was not available. The estimated concentration was calculated based on the maximum total chromium concentration of 400 mg/kg multiplied by the assumed hexavalent chromium percentage of 1.5%. The estimated hexavalent chromium concentration is below the industrial soil RSL (6.3 mg/kg), and chromium is therefore not identified as a COPC for Site soils. The maximum detections of the following chemicals in on-Site soil exceeded their respective screening levels, and thus were identified as COPCs in soil:

- 2,3,7,8-TCDD-TEQ
- arsenic
- cobalt
- manganese
- nickel
- thallium
- vanadium
- PCBs
- TPH- diesel range organics (DRO) (C10-C20)
- benzo(a)pyrene
- benzo(b)fluoranthene
- dibenz(a,h)anthracene
- benzo(a)anthracene
- benzo(k)fluoranthene
- chrysene*
- indeno(1,2,3-cd)pyrene
- naphthalene

While the maximum detection of chrysene was less than its RSL, it was included as a COPC because the other potentially carcinogenic PAHs in Site soil were identified as COPCs (listed above with an asterisk *). The maximum concentrations of many of the inorganics and all of the pesticides, VOCs, and SVOCs, except for a limited number of PAHs, were below their respective RSLs. Therefore, these chemicals were not identified as COPCs and do not require further evaluation.

Groundwater

As discussed in Section 2.2.1, potentially complete exposure pathways for Site groundwater include discharge to the Anacostia River, vapor intrusion from groundwater into an excavation trench, and potential vapor intrusion into the air of a future building if it were constructed in the vicinity of VOCs detected above screening levels in groundwater. The groundwater discharge (groundwater-to-surface water) pathway is discussed in Section 5.6. COPCs for the vapor intrusion into indoor air pathway are discussed in **Attachment B.** The excavation trench pathway is discussed below.

COPCs in UWZ groundwater were selected to evaluate vapor intrusion to an excavation trench pathway; these COPCs are listed in **Table 3-14**. There are no published screening levels directly applicable to this pathway. Vapor Intrusion Screening Levels (VISLs) are applicable to indoor air and are thus overly conservative for the excavation trench pathway. USEPA tapwater RSLs are derived assuming consumption of site-derived water as drinking water and are also conservative for the inhalation of trench air pathway. Consistent with the Risk Assessment Work Plan Addendum (AECOM, 2016d), maximum detected concentrations of VOCs were compared to the USEPA RSLs for tapwater based on a cancer risk level of $1x10^{-6}$ for potential carcinogens and a target HQ of 0.1 for potential noncarcinogens (See **Table 3-10**). The following VOCs were identified as COPCs for the excavation trench air pathway:

- bromodichloromethane
- tert-butyl alcohol
- chloroform
- methyl tert-butyl ether (MTBE)
- tetrachloroethylene
- trichloroethene
- vinyl chloride

3.2.2.2 Waterside Investigation Area COPC Selection

Waterside Investigation Area Fringe Surface Sediment

The routes of potential exposure to chemicals in fringe surface sediment were considered to identify appropriate sediment RBSLs. As identified in the CSM, human receptors who visit the Anacostia River may incidentally ingest and dermally contact fringe surface sediment while recreating at the River. A comprehensive set of risk-based sediment screening levels based on occasional direct contact exposures is not available from either USEPA or DOEE. In the absence of sediment screening levels based on direct contact exposures, the USEPA RSLs for residential soil were used to identify COPCs for the recreational receptor fringe surface sediment direct contact scenarios (see **Table 3-9**). The residential soil RSLs are derived assuming daily year-round soil contact by an adult and child via incidental ingestion, dermal contact, and inhalation of soil-derived dusts and vapors for 26 years. Because exposure to fringe surface sediment is expected to be much less frequent and intensive than exposure to residential soil, the residential soil RSLs represent highly conservative screening levels for fringe surface sediment. Consistent with the approach used for soil, the RSLs corresponding to a target risk of $1x10^{-6}$ for potential carcinogens and a target HQ of 0.1 for potential noncarcinogens were used.

Table 3-15 presents the COPC screening for Waterside Investigation Area fringe surface sediment. The following COPCs were identified:

- 2,3,7,8-TCDD-TEQ
- aluminum
- antimony
- arsenic
- cobalt
- manganese
- nickel
- thallium
- vanadium
- PCBs (Aroclors)
- benzo(a)anthracene
- benzo(a)pyrene
- benzo(b)fluoranthene
- benzo(k)fluoranthene*
- chrysene*
- dibenz(a,h)anthracene
- indeno(1,2,3-cd)pyrene
- TPH (C10-C28)

While the maximum detections of benzo(k)fluoranthene and chrysene are less than their respective RSLs, they are included as COPCs because the other potentially carcinogenic PAHs in fringe surface sediment were identified as COPCs (listed above with an asterisk *).

Waterside Investigation Area Surface Water

The routes of potential exposure to chemicals in surface water were considered to identify appropriate RBSLs. As identified in the CSM, receptors who visit the River may incidentally ingest and dermally contact surface water while recreating at the River. A comprehensive set of risk-based surface water screening levels based on occasional direct contact exposures is not available from either USEPA or DOEE. In the absence of relevant surface water screening levels, the following hierarchy of surface water screening level guidance was used for COPC screening (see **Table 3-11**):

1. DOEE, Title 21 of the District of Columbia Municipal Regulations, Chapter 11, Water Quality Standards. Effective November 1, 2013 (DOEE, 2013).
2. USEPA, National Recommended Water Quality Criteria (NRWQC) for Priority Pollutants. Value for Human Health for the consumption of organisms, accessed August 2018 (USEPA, 2018c).
3. USEPA, RSL for tapwater, November 2018 (USEPA, 2018a).

The DOEE water quality standards and USEPA NRWQC are based on protection of fish and shellfish that may be consumed by humans. These criteria are typically derived by relating acceptable risk-based concentrations in fish tissue to concentrations in surface water via a bioaccumulation factor (BAF). As such, the use of these criteria, as well as the RSLs for tapwater, to select COPCs for evaluating occasional direct contact exposures to surface water is highly conservative. **Table 3-11** identifies the three sets of surface water criteria, and the criterion that was selected for screening.

Table 3-16 presents the COPC screening for Waterside Investigation Area surface water. The following COPCs were identified:

- 2,3,7,8-TCDD-TEQ
- arsenic
- cobalt
- manganese
- 4,4'-DDT

While total PCBs (Aroclors) was not detected in Waterside Investigation Area or background surface water samples, the analytical method that was used (Method 8082) achieves a detection limit of approximately 0.01 micrograms per liter (µg/L), which is above the applicable surface water screening level of 0.000064 µg/L for total PCBs. Therefore, total PCBs (Aroclors) was conservatively identified as a surface water COPC and carried forward in the risk calculations assuming it is present at the lowest reporting limit achieved for surface water (0.0094 µg/L).

Fish Tissue

USEPA no longer provides default RSLs for fish tissue ingestion, and recommends they be calculated using the online RSL calculator tool (USEPA, 2018d). Therefore, fish tissue RSLs were calculated using the conservative historical default fish ingestion rate of 54 grams per day that was previously used by USEPA for RSL development. **Table 3-12** presents the fish tissue RSLs corresponding to a target risk level of 10^{-6} and a hazard index (HI) of 0.1. **Tables 3-17** to **3-21** present the comparison of maximum detected fish tissue concentrations in each of the five reaches to the fish RSLs. The following COPCs were selected:

COPC	Anacostia River (Tidal)		Potomac River		Upstream Non-Tidal Anacostia
	Upper	Lower	Upper	Lower	
Dioxins and Furans					
2,3,7,8-TCDD-TEQ	[a]	[a]	[a]	[a]	X
PCBs					
Total PCBs (congeners)	X	X	X	X	X
PCB-TEQ	X	X	X	X	X
Inorganics					
Arsenic		X	X	X	X
Cobalt					X
Mercury	X	X	X	X	X
Thallium					X
Pesticides					
4,4'-Dichlorodiphenyldichloro-ethane (DDD)	X	X	X	X	X
4,4'-Dichlorodiphenyldichloro-ethylene (DDE)	X	X	X	X	X
Aldrin	X	X	X		X
alpha-Chlordane	X	X	X	X	X [b]
beta-Hexachlorocyclohexane			X		
cis-Nonachlor	X	X	X		
Dieldrin	X	X	X	X	X
gamma-Chlordane	X	X	X	X	
Heptachlor epoxide	X	X	X	X	X
Hexachlorobenzene			X		
Mirex	X	X	X		
Oxychlordane	X	X	X	X	
trans-Nonachlor	X	X	X	X	

Notes:
[a] Data are not available.
[b] Represents total chlordane.

3.2.3 COPC Summary

Table 3-23 presents a summary of the COPCs. Soil COPCs include dioxins and furans, several inorganics, PCBs, DRO, naphthalene, and potentially carcinogenic PAHs. Several VOCs were identified as COPCs for the groundwater to air excavation trench pathway and for the hypothetical future vapor intrusion to indoor air pathway. **Table 3-23** also presents a summary of the Waterside Investigation Area COPCs, which include dioxins and furans, inorganics, pesticides, PCBs, and carcinogenic PAHs. These COPCs were carried forward in the risk calculations for the BHHRA.

4 Dose-Response Assessment

The purpose of the dose-response assessment is to identify the types of adverse health effects that may be associated with potential exposure to a chemical, and to define the relationship between the dose of a chemical and the likelihood and magnitude of an adverse effect (response) (USEPA 1989a). Combining the results of the toxicity assessment with information on the magnitude of potential exposure (developed in the exposure assessment) yields an estimate of potential risk (provided in the risk characterization).

Adverse effects are classified by USEPA as potentially carcinogenic or noncarcinogenic (i.e., potential effects other than cancer). Dose-response relationships are typically defined by USEPA for oral exposure and for exposure by inhalation. Because of the scarcity of toxicological data and established values for the dermal route of exposure, oral toxicity values are used to assess dermal exposures, with an appropriate adjustment for differences in absorption (USEPA, 2004a).

For evaluation of potential noncancer effects, USEPA has developed oral reference doses (RfDs) and inhalation reference concentrations (RfCs) for effects known or assumed to be produced through a nonlinear “mode of action” (USEPA, 2018b). Mode of action is defined as a sequence of key events and processes, starting with interaction of an agent with a cell and resulting in cancer formation. The RfDs and RfCs were developed based on the assumption that thresholds exist for certain toxic effects (such as gastrointestinal effects). The RfD is expressed in units of milligrams of a chemical per kilogram of body weight per day (mg/kg-day), and the RfC is expressed in units of milligrams of a chemical per cubic meter of air (mg/m^3). In general, the RfDs and RfCs are estimates (with uncertainty spanning perhaps an order of magnitude) of a daily exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime. For evaluation of potential noncarcinogenic effects, exposures are characterized as chronic (i.e., lasting longer than 7 years) or subchronic (i.e., lasting 7 years or less). Consistent with the Science Advisory Board (SAB) recommendation cited in the soil screening-level guidance (USEPA, 2002c), a child of 1 to 6 years is considered to have a chronic exposure.[10] The construction worker scenario evaluated in this BHHRA is a 1-year, sub-chronic exposure scenario.

[10] The SAB noted that the combination of the 6-year childhood exposure with a chronic RfD may be appropriate for chemicals with toxic endpoints specific to children or with steep dose-response curves but is likely to be over-protective for most chemicals (USEPA, 1993c).

For evaluation of potential cancer effects, USEPA has characterized the weight of evidence for human carcinogenicity and developed oral slope factors and oral and inhalation unit risks (USEPA, 2018b). USEPA presents the quantitative dose-response estimates in three ways: (1) the slope factor is presented as the risk per (mg/kg-day); (2) the unit risk is the quantitative estimate in terms of either ingestion risk per µg/L of drinking water or inhalation risk per microgram per cubic meter (µg/m^3) of air breathed; and (3) a chemical concentration in drinking water or air is based on predicted cancer risks of 1 in 10,000, 1 in 100,000, or 1 in 1,000,000.

The dose-response assessment is presented in six subsections. Section 4.1 describes the basis of the dose-response relationships characterized by USEPA. Section 4.2 describes the sources of toxicity values applied in this BHHRA. Section 4.3 describes the toxicity values developed by USEPA for the evaluation of potential noncarcinogenic effects. Section 4.4 describes the toxicity values developed by USEPA for the evaluation of potential carcinogenic effects. Section 4.5 discusses the use of oral toxicity values and absorption adjustment factors to estimate dermal exposure. Section 4.6 discusses specific toxicity approaches used for certain chemicals.

4.1 Basis of Dose-Response Relationships

The dose-response relationships characterized by USEPA toxicity values are often determined from studies of laboratory animals conducted under controlled conditions designed to minimize responses due to confounding variables and are conducted at relatively high dose levels to ensure that responses can be observed using as few animals as possible in the experiments. Mathematical models and uncertainty factors (UFs) are used to extrapolate the relatively high doses administered to animals to predict potential human responses at dose levels far below those tested in animals.

Humans are typically exposed to chemicals in the environment at levels much lower than those tested in animals. These low doses may be detoxified or rendered inactive by the myriad of protective mechanisms that are present in humans (Ames et al., 1987) and which may not function at the high dose levels used in animal experiments. Moreover, as noted by USEPA (1993b), “in the case of systemic toxicity, however, organic homeostatic, compensating, and adaptive mechanisms exist that must be overcome before a toxic endpoint is manifested.” Therefore, the results of these animal studies may only be of limited use in accurately predicting a dose-response relationship in humans (USEPA, 1989a). In fact, many effects seen in laboratory animals at the high doses tested are not seen in human exposures to chemicals. For example, while PCBs have been demonstrated to produce tumors in animals, human epidemiological data do not support the carcinogenicity of PCBs (Shields, 2006; Golden et al. 2003, Golden and Kimbrough, 2009).

Despite these uncertainties, and with the goal of being protective of human health, USEPA assumes that the results of animal toxicity studies are predictive of potential toxicity in humans. Moreover, based on the assumption that humans are more sensitive to chemicals than laboratory animals, USEPA incorporates conservative assumptions and UFs when deriving numerical toxicity values from laboratory studies, as discussed in Sections 4.3 and 4.4. However, USEPA explicitly recognizes these extrapolations from high doses to low doses and from animal studies to predict responses in humans as uncertainties in the risk assessment process (USEPA, 1989a).

In some cases, data from human exposure to chemicals are used to develop dose-response values. However, these data also have uncertainties because often it is not possible to determine from human exposure studies whether one or more chemicals are responsible for the observed effects, and it is even more difficult to determine precise exposure levels (USEPA, 1989a). Moreover, where effects are observed in humans, they generally occur at high exposure levels (often in industrial settings), and it is difficult to predict potential human responses at the much lower dose levels that occur in environmental exposure scenarios (USEPA, 1989a).

4.2 Sources of Toxicity Data

The USEPA's (2003a) guidance regarding the relevant human health dose-response values for use in risk assessment was followed in this assessment using the following hierarchy:

- Tier 1 - USEPA's Integrated Risk Information System (IRIS), an online database of the Agency's most current, verified, consensus-based toxicity values (USEPA, 2018b)
- Tier 2 - USEPA's National Center for Environmental Assessment (NCEA), Superfund Health Risk Technical Support Center Provisional Peer Reviewed Toxicity Values (PPRTV) (USEPA, 2018e)
- Tier 3 - Other sources of information, such as the PPRTV screening toxicity values, California Environmental Protection Agency (CalEPA), the Agency for Toxic Substances and Disease Registry (ATSDR) Minimal Risk Levels (MRLs), and the Health Effects Assessment Summary Tables (HEAST) (USEPA, 1997a), with priority given to those sources that are most current, transparent, and have been peer reviewed (USEPA, 2003a)

Numerical toxicity values used in this assessment are oral RfDs, oral cancer slope factors (CSFs), inhalation RfCs, and inhalation unit risk factors (URFs). **Tables 4-1** (oral/dermal) and **4-2** (inhalation) present the noncancer toxicity values used in this BHHRA, and **Tables 4-3** (oral/dermal) and **4-4** (inhalation) present the cancer toxicity values used in this BHHRA. As indicated in **Tables 4-1** through **4-4**, the majority of the toxicity values are Tier 1 values found in the IRIS database (USEPA, 2018b).

COPCs for which Tier 2 and Tier 3 dose-response values are used are listed in the table below. For many, IRIS (Tier 1) values are available for some values, as noted in the table.

Tier 2 and Tier 3 Dose-Response Values Used in the BHHRA				
COPC	**Oral RfD**	**RfC**	**Oral CSF**	**URF**
2,3,7,8-TCDD-TEQ	Tier 1 IRIS	Tier 3 CalEPA	Tier 3 CalEPA	Tier 3 CalEPA
4,4-DDD	Tier 3 PPRTV screening value	No value available	Tier 1 IRIS	Tier 3 CalEPA
4,4-DDE	Tier 3 PPRTV screening value	No value available	Tier 1 IRIS	Tier 3 CalEPA
Aluminum	Tier 2 PPRTV	Tier 2 PPRTV	No value available	No value available
Arsenic (inorganic)	Tier 1 IRIS	Tier 3 CalEPA	Tier 1 IRIS	Tier 1 IRIS
Arsenic (organic)[a]	Tier 3 ATSDR	No value available	No value available	No value available
Bromodichloromethane	Not a COPC for oral/dermal	No value available	Not a COPC for oral/dermal	Tier 3 CalEPA
Chloroform	Not a COPC for oral/dermal	Tier 3 ATSDR	Not a COPC for oral/dermal	Tier 1 IRIS
Cobalt	Tier 2 PPRTV	Tier 2 PPRTV	No value available	Tier 2 PPRTV
DRO	Tier 3 PPRTV screening value	Tier 3 PPRTV screening value	No value available	No value available
MTBE	Not a COPC for oral/dermal exposures	Tier 1 IRIS	Not a COPC for oral/dermal exposures	Tier 3 CalEPA
Mirex	Tier 1 IRIS	No value available	Tier 3 CalEPA	Tier 3 CalEPA
Naphthalene	Tier 1 IRIS	Tier 1 IRIS	No value available	Tier 3 CalEPA
Nickel	Tier 1 IRIS	Tier 3 ATSDR	No value available	Tier 3 CalEPA
Thallium	Tier 3 PPRTV screening value	No value available	No value available	No value available
Vanadium	Tier 1 IRIS	Tier 3 ATSDR	No value available	No value available
Notes: [a] Used in the evaluation of fish consumption exposure pathway only				

It should be noted that the Tier 2 and 3 values used in this BHHRA were also used by USEPA in RSL development (USEPA, 2018a).

When toxicity data were not available from any of the available sources, surrogates were assigned based on structurally and toxicologically similar chemicals. Surrogates were assigned as follows:

- Toxicity values for technical chlordane were used to evaluate chlordane isomers (alpha-chlordane, gamma-chlordane, cis-nonachlor, trans-nonachlor, oxychlordane)
- Toxicity values for isopropanol were used to evaluate tert-butyl alcohol

4.3 Noncarcinogenic Toxicity Assessment

Chemicals with known or potential noncarcinogenic effects are assumed to have a dose below which no adverse effect occurs or, conversely, above which an adverse effect may be seen. This dose is called the threshold dose. A conservative estimate of the true threshold dose is referred to as a No Observed Adverse Effect Level (NOAEL). The lowest dose at which an adverse effect has been observed is referred to as a Lowest Observed Adverse Effect Level (LOAEL). The NOAEL, or if not available, the LOAEL, is used as the point of departure (POD) for extrapolating from experimental data to predict a threshold level for humans. By applying UFs to the NOAEL or the LOAEL, USEPA has developed RfDs for chronic exposure to chemicals with noncarcinogenic effects (USEPA, 1997a, 2002f, 2018b).

In more recent derivations, USEPA has used a benchmark dose (BMD) approach to define the POD for an observed adverse outcome, or benchmark response, from experimental observations. The BMD approach provides a more quantitative alternative to the first step in the dose-response assessment than the current NOAEL/LOAEL process for noncancer health effects. Derivation of the BMD is a two-step process: (1) response data are modeled in the range of empirical observation; and then (2) extrapolation below the range of observation is accomplished by modeling. The POD for BMD modeling is the benchmark dose lower bound (BMDL), or the lower 95% bound on the dose/exposure associated with the benchmark response (i.e., adverse response), typically 10% above the control response. Using the BMDL accounts for the uncertainty inherent in a given study and ensures (with 95% confidence) that the target benchmark response is not exceeded. UFs are then applied to the BMDL, as in the case for the NOAEL/LOAEL approach, to derive an RfD.

In regulatory toxicity assessment, USEPA assumes that humans are as sensitive, or more sensitive, to the toxic effects of a chemical as the most sensitive species used in the laboratory studies. Moreover, the RfD or RfC is developed based on the most sensitive or critical adverse health effect observed in the study population, with the assumption that if the most critical effect is prevented, then all other potential toxic effects are prevented. UFs are applied to the BMDL or NOAEL (or LOAEL, when a NOAEL is unavailable) for this critical effect to account for uncertainties associated with the dose-response relationship. These include using an animal study to derive a human toxicity value, extrapolating from a LOAEL to a NOAEL, extrapolating from a subchronic (partial lifetime) to a chronic lifetime exposure, and evaluating sensitive subpopulations. Generally, a 10-fold UF is used to account for each of these uncertainties, although a UF of 3 can be used where uncertainty is lower; thus, the total UF can range from 3 to 10,000, although USEPA (2002f) recommends limiting the total combined UF for a chemical to 3,000. In addition, a UF or a modifying factor of up to 10 can be used to account for inadequacies in the database or other uncertainties. The UFs for the COPCs evaluated in this risk assessment range from 3 to 3,000. USEPA's standard UFs and the modifying factors are identified below (USEPA, 1993b).

Standard Uncertainty Factors:

- Use a 10-fold factor when extrapolating from valid experimental results in studies using prolonged exposure to average healthy humans. This factor is intended to account for the variation in sensitivity among the members of the human population and is referenced as "10H."
- Use an additional 10-fold factor when extrapolating from valid results of long-term studies on experimental animals when results of studies of human exposure are not available or are inadequate. This factor is intended to account for the uncertainty involved in extrapolating from animal data to humans and is referenced as "10A."
- Use an additional 10-fold factor when extrapolating from less than chronic results on experimental animals when there are no useful long-term human data. This factor is intended to account for the uncertainty involved in extrapolating from less than chronic NOAELs to chronic NOAELs and is referenced as "10S."
- Use an additional 10-fold factor when deriving an RfD from a LOAEL instead of a NOAEL. This factor is intended to account for the uncertainty involved in extrapolating from LOAELs to NOAELs and is referenced as "10L."

The final UF is derived by multiplying the individual UFs and rounding to one significant figure. Uncertainty and modifying factors that were applied to the COPCs included in this BHHRA are listed in **Tables 4-1** and **4-2**, which range from 3 (arsenic RfD, manganese RfD) to 10,000 (DRO RfD).

The resulting RfDs are conservative, i.e., health protective, because of the frequent use of multiple uncertainty and modifying factors. Consequently, an RfD provides reasonable certainty that no noncarcinogenic health effects are expected to occur, even for sensitive individuals and if daily exposures were to occur at the RfD level for a lifetime. As noted above, RfDs and exposure doses are expressed in mg/kg-day). The lower the RfD value, the lower the assumed threshold for effects, and the greater the assumed toxicity.

Table 4-1 summarizes the oral noncarcinogenic toxicity values (i.e., RfDs) and the corresponding critical effects for the COPCs. **Table 4-2** summarizes the inhalation noncarcinogenic toxicity values (i.e., RfCs) and the corresponding critical effects for COPCs. For each COPC, the chemical abstracts service number (CAS number), the dose-response value (RfD or RfC), and the reference for the toxicity value are presented. In addition, the USEPA confidence level in the value, the uncertainty factor, the modifying factor, the study animal, study method, target endpoint, or critical effects upon which the toxicity value is based are presented for each COPC, where available. USEPA's confidence in the toxicity value is based on confidence in the selected study and the extent of available toxicity information. Adjustments for dermal absorption are discussed in Section 4.5.

Subchronic toxicity values are applicable to the construction worker scenario for which exposures are expected to occur over a brief (e.g., 40-day) duration. Subchronic toxicity values are not generally found in IRIS. Therefore, chronic toxicity values were conservatively used to evaluate the construction worker pathway initially and were updated with subchronic toxicity values where warranted and available.[11] The noncancer toxicity values used to evaluate oral and inhalation exposures for the construction worker scenario are presented in **Tables 4-1** and **4-2**, respectively.

4.4 Carcinogenic Toxicity Assessment

USEPA has developed carcinogen risk assessment guidelines (USEPA, 2005b) that revise and replace the previous carcinogen risk assessment guidelines (USEPA, 1986). However, the carcinogen risk assessments for many of the chemicals listed in USEPA's IRIS database, including PCBs, still follow the classification system developed in the previous guidance (USEPA, 1986). The classification system in the previous guidance was developed according to the weight of evidence from epidemiologic and animal studies:

Group A Human Carcinogen (sufficient evidence of carcinogenicity in humans)

Group B Probable Human Carcinogen (B1 - limited evidence of carcinogenicity in humans; B2 – sufficient evidence of carcinogenicity in animals with inadequate or lack of evidence in humans)

[11] PCBs and vanadium were the only COPCs with exceedances for the construction worker based on chronic toxicity values. A subchronic RfD for PCBs is available and was therefore used. No subchronic toxicity data are available for vanadium.

Group C Possible Human Carcinogen (limited evidence of carcinogenicity in animals and inadequate or lack of human data)

Group D Not Classifiable as to Human Carcinogenicity (inadequate or no evidence)

Group E Evidence of Noncarcinogenicity for Humans (no evidence of carcinogenicity in adequate studies)

In the previous guidance, it was assumed that there is some finite level of risk associated with each non-zero dose. The USEPA has developed computerized models that extrapolate dose-response relations observed at the relatively high doses used in animal studies to the low dose levels encountered by humans in environmental situations. The mathematical models developed by USEPA assume no threshold and use both animal and human data (where available) to develop a potency estimate for a given chemical. The potency estimate for oral and dermal exposure, i.e., the CSF, is expressed in units of $(mg/kg\text{-}day)^{-1}$; the higher the CSF, the greater the carcinogenic potential.

USEPA (2005b) places greater emphasis on critically evaluating all available data from which a default linear low-dose extrapolation option may be invoked if needed in the absence of critical information. The guidance also emphasizes the consideration of mode of action data. As previously noted, mode of action is defined as a sequence of key events and processes, starting with interaction of an agent with a cell and resulting in cancer formation. Some modes of action are anticipated to be mutagenic and are assessed with a linear approach. Other modes of action may be modeled with either linear or nonlinear approaches after a rigorous analysis of available data under the guidance provided in the framework for mode of action analysis. USEPA (2005b) uses a weight of evidence narrative rather than the classification system that was used in the previous guidance. The following descriptors are recommended along with the weight of evidence narrative:

- **Carcinogenic to humans** – this descriptor indicates strong evidence of human carcinogenicity.
- **Likely to be carcinogenic to humans** – this descriptor is appropriate when the weight of evidence is adequate to demonstrate carcinogenic potential to humans.
- **Suggestive evidence of carcinogenic potential** – this descriptor is appropriate when the weight of evidence is suggestive of carcinogenicity; a concern for potential carcinogenic effects in humans is raised, but the data are judged not sufficient for a stronger conclusion.
- **Inadequate information to assess carcinogenic potential** – this descriptor is appropriate when available data are judged inadequate for applying one of the other descriptors.

- **Not likely to be carcinogenic to humans** – this descriptor is appropriate when the available data are considered robust for deciding that there is no basis for human hazard concern.

More than one descriptor can be used when a chemical's effects differ by dose or exposure route.

While these narrative descriptions represent important advances in carcinogen risk assessment, the approach has not generally been implemented for chemicals with toxicity values on IRIS. Therefore, the alphanumeric system is still presented on IRIS and is included here, as several COPCs remain classified under the older system.

Table 4-3 summarizes the oral toxicity information for the COPCs with presumed carcinogenic effects via the oral route of exposure. The CAS number, USEPA carcinogenicity class, the oral CSF, and the reference are provided. In addition, the study animal and route of exposure upon which the CSF is based are presented. Adjustments for dermal absorption are discussed in Section 4.5. **Table 4-4** presents the inhalation toxicity information for COPCs with presumed carcinogenic effects via the inhalation route of exposure.

4.4.1 Mutagenic Mode of Action

USEPA guidance for early life exposure to carcinogens (USEPA, 2005b) requires that potential risks from chemicals that act by a mutagenic mode of action be calculated differently than chemicals that do not act via a mutagenic mode of action. For carcinogens presumed to act via a mutagenic mode of action, dose-response values are generally based on the linearized multistage (LMS) model, which assumes that cancer risks are linear in the low-dose region (USEPA, 2005b, c). Consistent with the Cancer Guidelines and Supplemental Guidance for Assessing Susceptibility for Early-Life Exposure to Carcinogens (USEPA, 2005c), the application of age-dependent adjustment factors (ADAFs) for chemicals with a mutagenic mode of action has been used in the calculation of risk from specific chemicals, including potentially carcinogenic PAHs. While both trichloroethylene and vinyl chloride are potentially mutagenic, they are COPCs only for the excavation trench air pathway for a construction worker and the vapor intrusion to indoor air pathway for an industrial worker, and thus ADAFs do not apply. The ADAFs applied to the potentially carcinogenic PAHs are listed below:

- Ages 0-2: ADAF = 10
- Ages 2-6: ADAF = 3
- Ages 6-16: ADAF = 3
- Ages >16: ADAF = 1

Age-weighted ADAFs were calculated for the young child and older child/teen group based on the exposure durations. For the reasonable maximum exposure (RME) scenarios, the ADAFs for the entire age span of the receptor were averaged. The ADAFs used for the RME scenarios were also used for the central tendency exposure (CTE) scenarios. The derivation of the ADAFs for each age range is presented below.

Receptor Age (years)	1<7	7<19
RME Exposure Duration (years)	6	12
CTE Exposure Duration (years)	3	6
Age Range	**ADAF**	
0<1		
1<2	10	
2<3	3	
3<4	3	
4<5	3	
5<6	3	
6<7	3	
7<8		3
8<9		3
9<10		3
10<11		3
11<12		3
12<13		3
13<14		3
14<15		3
15<16		3
16<17		1
17<18		1
18<19		1
RME and CTE ADAF [a]	**4.2**	**2.5**

Notes:
[a] RME ADAF is the average of the ADAFs for the receptors assumed exposure duration, which is the same as the age span of the receptor. The RME ADAFs were also applied to the CTE scenarios.

4.5 Absorption Adjustment for Dermal Toxicity Values

As there are no dermal dose-response values available for the COPCs addressed in this BHHRA, oral dose-response values were used to evaluate dermal exposures. The equation for calculating dermal absorption gives rise to an absorbed dose, making it necessary to adjust the oral toxicity factor (which reflects an administered dose rather than an absorbed dose). This adjustment accounts for the gastrointestinal absorption efficiency in the critical study that forms the basis of the RfD or CSF. For example, when oral absorption in the critical study is essentially complete (i.e., 100%), the absorbed dose is equivalent to the administered dose, and therefore no adjustment is necessary. Adjustment is only recommended when gastrointestinal absorption is less than 50%. For organic chemicals, no adjustment is considered necessary, since their gastrointestinal absorption is generally high. Five of the inorganics evaluated in this risk assessment (antimony, manganese, mercury, nickel, and vanadium) require adjustment, as indicated in **Table 4-1**. USEPA (2004a, Exhibit 4-1) provides recommended adjustment factors for oral dose-response values.

4.6 Chemical-Specific Approaches

The toxicity assessment approach used for COPCs with specific toxicological issues is discussed in this section:

- Dioxins and Furans (Section 4.6.1)
- PCBs (Section 4.6.2)
- PAHs (Section 4.6.3)

4.6.1 Dioxins and Furans

Dioxins and furans, expressed as 2,3,7,8-TCDD-TEQ, were identified as COPCs in fringe surface sediment, surface water, and Upstream Non-Tidal Anacostia River fish tissue. The approaches used to estimate potential carcinogenic risks and noncarcinogenic hazards associated with 2,3,7,8-TCDD-TEQ are described below. Because dioxins and furans occur in complex mixtures, the toxicity of 2,3,7,8-TCDD, by far the most extensively studied of the group, is used as a reference for the other members of this family of chlorinated chemicals. Based on their ability to bind to the aryl hydrocarbon (Ah) receptor, seven 2,3,7,8-chlorinated dioxin and ten 2,3,7,8-chlorinated furan congeners are assumed to have a mechanism of toxicity similar to that of TCDD. Toxicity equivalency factors (TEFs) have been developed by the World Health Organization (WHO) (Van den Berg et al., 2006) to equate the toxicity of each dioxin-like congener to that of TCDD. TEFs have been identified for 17 dioxins and furans, ranging from 0.0003 to 1, as shown below. In December 2010, USEPA published guidance that adopts the 2005 WHO mammalian TEFs for risk assessment (USEPA, 2010).

Chemical	WHO 2005 Toxicity Equivalency Factor (TEF)
Chlorinated dibenzo-p-dioxins	
2,3,7,8-TCDD	1
1,2,3,7,8-PeCDD	1
1,2,3,4,7,8-HxCDD	0.1
1,2,3,6,7,8-HxCDD	0.1
1,2,3,7,8,9-HxCDD	0.1
1,2,3,4,6,7,8-HpCDD	0.01
OCDD	0.0003
Chlorinated dibenzofurans	
2,3,7,8-TCDF	0.1
1,2,3,7,8-PeCDF	0.03
2,3,4,7,8-PeCDF	0.3
1,2,3,4,7,8-HxCDF	0.1
1,2,3,6,7,8-HxCDF	0.1
1,2,3,7,8,9-HxCDF	0.1
2,3,4,6,7,8-HxCDF	0.1
1,2,3,4,6,7,8-HpCDF	0.01
1,2,3,4,7,8,9-HpCDF	0.01
OCDF	0.0003
Source: Van den Berg et al., 2006; USEPA, 2010.	

By multiplying the concentration of each dioxin-like congener in an environmental sample by its TEF and summing the results, a 2,3,7,8-TCDD-TEQ concentration can be calculated for the sample.

Due to the lack of Tier 1 or 2 toxicity factors, the CalEPA toxicity values for 2,3,7,8-TCDD were used to evaluate potential carcinogenic effects of 2,3,7,8-TCDD-TEQ via the oral, dermal, and inhalation pathways, as well as noncarcinogenic effects via the inhalation route of exposure (CalEPA, 2018). The USEPA Tier 1 RfD for TCDD was used to estimate the potential noncancer hazard associated with 2,3,7,8-TCDD-TEQ via oral and dermal exposure (USEPA, 2018b).

4.6.2 Polychlorinated Biphenyls

PCBs were identified as a COPC in soil, fringe surface sediment, surface water, and fish tissue. For abiotic media (soil, fringe surface sediment, and surface water), PCBs were evaluated as total PCBs (sum of Aroclors). For biotic media (fish tissue), PCBs were evaluated as both total PCBs (sum of congeners) and as PCB-TEQ. This approach recognizes two potential mechanisms of toxicity and the potential for enrichment of certain presumed dioxin-like congeners in biotic media (USEPA, 2010, 2018b). Therefore, for the angler receptor who is assumed to eat fish, two separate PCB cancer risks and noncancer hazards are calculated, one for total PCBs and one for PCB-TEQ. Therefore, for fish consumption, the BHHRA presents two separate estimates of cumulative cancer risks, one based on total PCBs, which includes all COPCs except PCB-TEQ, and one based on PCB-TEQ, which includes all COPCs except total PCBs. The uncertainty associated with the PCB toxicity approaches is discussed in the uncertainty analysis (Section 7). The approaches used to estimate potential carcinogenic risks and noncarcinogenic hazards associated with PCBs are described below.

4.6.2.1 Total PCBs Approach

For the total PCBs approach, the potential cancer risks and noncancer hazards posed by PCBs were calculated using the toxicity factors published on IRIS for PCB mixtures and specific Aroclors (USEPA, 2018b). The approach for evaluating carcinogenic effects is described first, followed by noncarcinogenic effects.

Carcinogenic Effects

USEPA provides three tiers of oral CSFs for evaluation of total PCBs: (1) high risk and persistence, (2) low risk and persistence, and (3) lowest risk and persistence (USEPA, 2018b). The choice of CSF depends on the route and medium of exposure and PCB chlorine content (USEPA, 2018b), as shown below. The CSFs are derived from animal cancer bioassay studies, and because mixtures of PCBs were used, the toxicity observed is the result of the combined effects of the mixtures on the whole animal (including presumed dioxin-like effects, as discussed in the uncertainty analysis).

Scenario	Upper-Bound Slope Factor (mg/kg-day)$^{-1}$	Central-Estimate Slope Factor (mg/kg-day)$^{-1}$	Slope Factor Basis	Criteria for Use:
High Risk and Persistence	2	1	Several studies on carcinogenicity of Aroclor 1260 and 1254	• Food chain exposure • Sediment or soil ingestion • Dust or aerosol inhalation • Dermal exposure, if an absorption factor has been applied • Presence of dioxin-like, tumor-promoting, or persistent congeners • Early-life exposure (all pathways and mixtures)
Low Risk and Persistence	0.4	0.3	Several studies of carcinogenicity of Aroclor 1242	• Ingestion of water-soluble congeners • Inhalation of evaporated congeners • Dermal exposure if no absorption factor has been applied
Lowest Risk and Persistence	0.07	0.04	Several studies of carcinogenicity of Aroclor 1016	• Congener or isomer analyses verify that congeners with more than 4 chlorines comprise less than 0.5% of total PCBs.
Source: USEPA, 2018b.				

Cancer risks via oral and dermal routes associated with total PCBs were evaluated as follows:

- Ingestion of soil, fringe surface sediment, and fish tissue, and dermal contact with soil and fringe surface sediment: high-risk and persistence, upper-bound CSF of 2 (mg/kg-day)$^{-1}$
- Ingestion of and dermal contact with surface water: low risk and persistence, upper-bound CSF of 0.4 (mg/kg-day)$^{-1}$

Inhalation URFs for PCBs are derived from the oral CSFs above assuming an inhalation rate of 20 mg/m^3 per day and a body weight of 70 kilograms (USEPA, 2018b). Consistent with the USEPA hierarchy for assigning a PCB slope factor by exposure pathway, the high risk and persistence values are applicable to the dust inhalation pathway (USEPA, 2018b). Therefore, the high risk and persistence upper-bound CSF was used to derive the URF. The use of the upper-bound CSF for the CTE scenario is conservative, as discussed in the uncertainty analysis in Section 7 below.

Noncarcinogenic Effects

USEPA has not developed an oral RfD for PCBs as a class;[12] however, USEPA has conducted threshold effect assessments for the following individual PCB mixtures: Aroclor 1254, 1016, and 1248. The USEPA provides an oral RfD of 2E-05 mg/kg-day for Aroclor 1254 and an oral RfD of 7E-05 mg/kg-day for Aroclor 1016. USEPA reviewed information on Aroclor 1248 but did not derive an RfD. The Aroclor oral RfDs on IRIS (USEPA, 2018b) were used to evaluate potential noncarcinogenic effects from PCBs. Although no specific guidance has been provided by USEPA or others concerning whether to use the oral RfD for Aroclor 1016 or Aroclor 1254, it is reasonable and scientifically valid to use the oral RfD for the Aroclor that most closely approximates the congener composition in the environmental media being evaluated. The RfD for Aroclor 1254 was used for this BHHRA based on the available data for Aroclor patterns in soil and sediment. PCBs in soil and River sediment samples collected adjacent to the Site were identified by Method 8082 as primarily an Aroclor 1248 and Aroclor 1260 mix, and Aroclor 1254 is midway between 1248 and 1260 in congener/homologue range.

The RfD for Aroclor 1254 of 2E-5 mg/kg-day is based on a subchronic toxicity study, with a total UF of 300, 10 for sensitive individuals, 3 for extrapolation from animals to humans, 3 for the use of a minimal LOAEL and 3 for extrapolation from a subchronic to chronic exposure duration (USEPA, 2018b). Therefore, the UF of 3 for extrapolation from subchronic to chronic exposure duration is removed to derive a subchronic RfD of 5E-5 mg/kg-day for the construction worker scenario (LOAEL of 5E-3 mg/kg-day divided by the remaining uncertainty factor of 100).

4.6.2.2 Dioxin-Like PCBs Approach

Certain PCB congeners have been identified as having a mechanism of toxicity similar to that of 2,3,7,8-TCDD (USEPA, 1996, 2010; Van den Berg et al., 2006). The designation as a “dioxin-like compound” is based on Ah receptor binding and similarities in biochemical activity and bioaccumulation potential to 2,3,7,8-TCDD. Twelve coplanar PCBs with four or more chlorines with one or no substitutions at ortho positions have been identified as having potential dioxin-like toxicity, and TEFs were developed to equate the toxicity of each dioxin-like PCB congener to that of 2,3,7,8-TCDD (Van den Berg et al., 2006). The “coplanar” PCBs lack ortho chlorines on both rings, allowing the rings to orient in the same plane, but this conformation is not rigid. USEPA’s December 2010 guidance adopts the 2005 WHO mammalian TEFs for the 12 coplanar PCBs (USEPA, 2010). The TEFs for dioxin-like PCBs are shown below.

---

[12] An IRIS assessment of the potential noncarcinogenic effects of PCB mixtures is underway (USEPA, 2018b).

Chemical	WHO 2005 Toxicity Equivalency Factor (TEF)
Non-ortho–substituted PCBs	
3,3’,4,4’-tetraCB (PCB 77)	0.0001
3,4,4’,5-tetraCB (PCB 81)	0.0003
3,3’,4,4’,5-pentaCB (PCB 126)	0.1
3,3,’4,4’,5,5’-hexaCB (PCB 169)	0.03
Mono-ortho–substituted PCBs	
2,3,3’,4,4’-pentaCB (PCB 105)	0.00003
2,3,4,4’,5-pentaCB (PCB 114)	0.00003
2,3’,4,4’,5-pentaCB (PCB 118)	0.00003
2’,3,4,4’,5-pentaCB (PCB 123)	0.00003
2,3,3’,4,4’,5-hexaCB (PCB 156)	0.00003
2,3,3’,4,4’,5’-hexaCB (PCB 157)	0.00003
2,3’,4,4’,5,5’-hexaCB (PCB 167)	0.00003
2,3,3’,4,4’,5,5’-heptaCB (PCB 189)	0.00003

The potential cancer risk posed by PCB-TEQ via fish consumption was evaluated in the BHHRA using the CSF for 2,3,7,8-TCDD of 130,000 (mg/kg-day)$^{-1}$.

Noncarcinogenic Effects

The oral RfD of 7E-10 mg/kg-day derived for 2,3,7,8-TCDD (USEPA, 2018b) was used to evaluate the potential noncarcinogenic effects of PCB-TEQ via fish consumption.

To avoid double counting of PCB risks, two separate sets of cancer risks and noncancer hazards were derived for the fish consumption scenario, with one set based on the toxicity factors for total PCBs and the other based on the toxicity factors for dioxin-like PCBs as PCB-TEQ.[13]

4.6.3 Polycyclic Aromatic Hydrocarbons

The following potentially carcinogenic PAHs were identified as COPCs in fringe surface sediment and in soil:

[13] Summing total PCB and PCB-TEQ cancer risks overestimates the risk posed by an environmental PCB mixture, as coplanar PCBs were present in the commercial Aroclor mixture used to derive the total PCBs CSF; hence, there is “double counting” of the risk posed by the coplanar PCBs if total PCB and PCB-TEQ risks are summed.

- Benz(a)anthracene
- Benzo(a)pyrene
- Benzo(b)fluoranthene
- Benzo(k)fluoranthene
- Chrysene
- Dibenz(a,h)anthracene
- Indeno(1,2,3-cd)pyrene

Benzo(a)pyrene (BaP) is the most studied of the PAHs and the only chemical in the group for which rodent bioassay data are considered by USEPA to be adequate for estimating an oral CSF. Therefore, the carcinogenic potency of the other PAHs with presumed carcinogenic effects was evaluated relative to BaP using relative potency factors (RPFs) (USEPA, 1993d). The current USEPA RPFs for the seven potentially carcinogenic PAHs are shown below. By multiplying the BaP CSF by each of the RPFs, a PAH-specific oral CSF can be calculated. The resulting CSFs applied in the BHHRA are shown below.

Chemical	Relative Potency Factor (USEPA, 1993d)	Oral Cancer Slope Factor $(mg/kg\text{-}day)^{-1}$	CSF Source
Benzo(a)pyrene	1	1	USEPA, 2018b
Benzo(a)anthracene	0.1	0.1	BaP CSF x RPF
Benzo(b)fluoranthene	0.1	0.1	BaP CSF x RPF
Benzo(k)fluoranthene	0.01	0.01	BaP CSF x RPF
Chrysene	0.001	0.001	BaP CSF x RPF
Dibenz(a,h)anthracene	1	1	BaP CSF x RPF
Indeno(1,2,3-c,d)pyrene	0.1	0.1	BaP CSF x RPF

An RfD is available from IRIS (USEPA, 2018b) for BaP. Currently, oral RfDs are not available for the other potentially carcinogenic PAHs from USEPA's hierarchy of sources (USEPA, 2003a). Therefore, oral RfDs were not assigned to the other potentially carcinogenic PAHs.

5 Exposure Assessment

The objective of the exposure assessment is to estimate the magnitude, frequency, duration, and routes of current and reasonably anticipated future human exposure to COPCs associated with the Study Area. The extent of a receptor's exposure is estimated by identifying exposure scenarios that describe the potential pathways of exposure to COPCs and the specific activities and behaviors (e.g., wading, fishing) of individuals that might lead to contact with COPCs in the environment.

USEPA guidance documents stress the importance of using data that represent the characteristics of the local population(s) and site when possible and appropriate (USEPA, 1989a, b, 1998, 2000, 2011). Default exposure assumptions, which are often intentionally conservative, may be appropriate when site-specific data are lacking, or when there is little reason to believe site conditions and/or receptor characteristics differ substantively from the default (e.g., human body weight, lifetime). Consistent with USEPA guidance and the approved Risk Assessment Work Plans (AECOM, 2012, 2016d), the exposure assessment for the Study Area utilizes both site-specific and default assumptions.

This section is organized as follows:

- Section 5.1 discusses potential exposure scenarios, based on the CSM presented in Section 2.2, including the potentially affected media and the pathways by which people may be exposed to Study Area media.
- Section 5.2 presents the methods used to quantify potential exposures for each potential exposure scenario.
- Section 5.3 identifies the exposure parameters and values used to quantify potential exposures.
- Section 5.4 presents chemical-specific parameters.
- Section 5.5 describes EPCs.
- Section 5.6 presents the groundwater-to-surface water screening evaluation.

5.1 Identification of Potential Exposure Scenarios

Exposure scenarios were developed based on the BHHRA CSM, as described in Section 2.2. Both Waterside and Landside exposure scenarios were evaluated. **Table 5-1** presents a summary of the receptors and exposure scenarios evaluated in the BHHRA. Because of the differences in activity patterns and sensitivity to exposures, three age groups were evaluated (USEPA, 2014a):[14]

- Young child age 1 to 6 years (from 1 up to the 7th birthday, 1 to <7),
- Older child/teen age 7 to 18 years (from 7 up to the 19th birthday, 7 to <19), and
- Adults (>18 years of age).

For carcinogenic risk characterization, which assumes that effects are additive over a lifetime, potential risks for the young child and adult age groups were calculated separately, and then summed to estimate the total potential lifetime excess cancer risk for the receptor. For noncarcinogenic risk characterization, effects were evaluated over the period of exposure. Therefore, noncancer hazards were calculated and presented separately for the young child, older child, and adult age groups.

5.1.1 Landside Investigation Area

The Site is completely surrounded by a fence with two guarded entrances. The guard stations are manned 24 hours a day, 7 days a week. The majority of the Site is covered by impervious material such as concrete or asphalt. Therefore, contact with on-Site media is unlikely under the current scenario. However, if conditions change in the future, it is possible that receptors may be potentially exposed to on-Site media.

Eight exposure areas were defined for soil and groundwater based on current Site use, as indicated below (see **Figure 3-1**):

- Hypothetical Future Park Land /Green Space
- Warehouse and Laydown Area
- Salvage Yard and Waste Storage Area
- Stores and Fleet Maintenance Area
- Offices and Parking Lot
- Substation #7
- Transformer Shop
- Vehicle Refueling Area

As discussed in Section 2.2.1, it is assumed that future recreational exposures will be limited to the western portion of the Site next to Anacostia Avenue (see **Figure 3-1**).

[14] Infants under 1 year of age are assumed to not be exposed to Study Area-related media; the potential contribution from early life exposures to lifetime risk is discussed in the uncertainty analysis.

5.1.1.1 Current/Future Construction Worker

A current and/or future construction worker (adult) may contact surface and subsurface soil during utility or other construction work requiring excavation into the subsurface. The construction worker is assumed to be exposed to soil via incidental ingestion and dermal contact as well as via inhalation of particulates and vapors from soil in outdoor air. The construction worker is also assumed to be potentially exposed to vapors migrating from the subsurface into the air of an excavation trench.

5.1.1.2 Future Outdoor Industrial Worker

It is assumed that in the future, should current Site configuration with respect to soil cover change, an industrial worker (adult) may contact surface soil. The industrial worker is assumed to be exposed to surface soil via incidental ingestion and dermal contact with surface soil, as well as inhalation of particulates and vapors from soil in outdoor air. The potential for future industrial workers to contact subsurface soil is discussed in the uncertainty analysis section.

5.1.1.3 Future Indoor Industrial Worker

It is assumed that if a future building were constructed in an area of the Site with groundwater concentrations above VISLs, a future indoor worker may be exposed via inhalation to vapors from groundwater due to vapor intrusion.

5.1.1.4 Future Recreational User

In the future, if Site access or security changes and the existing soil covers are removed, it is possible that recreational receptors will contact on-Site surface soil. Therefore, a future recreational user was evaluated (older child/teen). The recreational user is assumed to be potentially exposed to on-Site surface soil via incidental ingestion and dermal contact with surface soil, as well as inhalation of particulates and vapors from soil in outdoor air. It is assumed that future recreational exposures will be limited to the portion of the Site closest to the Anacostia River. The remainder of the Site will remain industrial/commercial with secure fencing and 24-hour security to deter trespassing. The Site will continue to be used as a service center into the foreseeable future due to the important role it serves in Pepco's electric transmission and distribution system.

5.1.2 Waterside Investigation Area

The public may access the Anacostia River at several locations, including parks, boat docks, and launches (**Figure 2-1**). Anacostia Park, a 1,200-acre unit of National Capital Parks – East, stretches 5 miles along the banks of the Anacostia River between the Fredrick Douglas Memorial Bridge and the DC-Maryland line. Within the park, the Anacostia Riverwalk Trail runs along the shoreline of the River, continuing beyond the north and south boundaries of the park. A public boat launch is located about 1.5 miles downstream from the Study Area.

Most of the eastern shoreline adjacent to the Site is stabilized with either sheet pile or rock wall. Dense vegetation along much of the shoreline adjacent to the Site may limit access in this area. Kingman Island divides the Anacostia Channel from Kingman Lake to the west and provides recreation opportunities via pier and trail access. The western shoreline is uniformly stabilized with a continuous rock wall with dense tree cover throughout.

As shown in **Figure 2-2**, recreational and worker exposure scenarios were identified in the CSM as potentially complete and warranting further evaluation. The receptors and applicable exposure pathways are summarized below.

5.1.2.1 Recreational Angler

The recreational angler (adult, older child/teen, young child) was assumed to be potentially exposed to COPCs via direct contact (incidental ingestion and dermal contact) with fringe surface sediment and surface water while fishing in the Waterside Investigation Area. It was also assumed that anglers keep and eat fish they catch in the Waterside Investigation Area and bring fish home to share with other members of the household (adult, older child/teen, young child).

Based on the survey results presented in Gibson and McClafferty (2005), some anglers may supplement a sizeable fraction of their diet with river fish. In addition to evaluating a recreational angler exposure scenario, the BHHRA also considers an exposure scenario involving a high-end consuming angler who fishes year-round and consumes two fish meals per week of Anacostia River fish in the uncertainty analysis (Section 7).

5.1.2.2 Swimmer/Wader

In addition to angling, visitors (adult, older child/teen, young child) to the River may wade, swim, boat, or engage in other activities that bring them into contact with river media. It was assumed that recreational receptors, including swimmers and waders, are exposed to COPCs via direct contact (incidental ingestion and dermal contact) with fringe surface sediment and surface water while wading or swimming in the Waterside Investigation Area. Potential exposures during boating are expected to be similar to those during wading and therefore were not evaluated separately.

5.1.2.3 Shoreline Workers

It was assumed that shoreline workers are exposed to COPCs via direct contact (incidental ingestion and dermal contact) with fringe surface sediment and surface water while working along the shore of the River next to the Site.

5.2 Quantification of Potential Exposures

To estimate human health risk from COPCs at the Site, it is necessary to estimate the potential exposure dose for each COPC. The exposure dose is estimated for each COPC for each exposure pathway by which the receptor is assumed to be exposed. Exposure dose equations combine the estimates of COPC concentrations in the environmental medium of interest with assumptions regarding the type and magnitude of each receptor's potential exposure to provide a numerical estimate of the exposure dose (intake). The exposure dose is defined as the amount of COPC taken into the receptor and is expressed in units of milligrams of COPC per kilogram of body weight per day (mg/kg-day) (USEPA, 1989a).

Exposure doses are defined differently for potential carcinogenic and noncarcinogenic effects. The chronic daily intake is used to estimate a receptor's potential average daily dose from exposure to a COPC with noncarcinogenic effects. According to USEPA (1989a), the chronic daily intake should be calculated by averaging the exposure dose over the period of time for which the receptor is assumed to be exposed. Therefore, the averaging period is the same as the exposure duration for COPCs with noncarcinogenic effects. For COPCs with potential carcinogenic effects, however, the chronic daily intake is calculated by averaging the exposure dose over the receptor's assumed lifetime (70 years). Therefore, the averaging period is the same as the receptor's assumed lifetime. The standardized equations for estimating a receptor's intake (both chronic and lifetime) are presented below. Receptor-specific parameters are discussed in Section 5.3.

5.2.1 Estimating Potential Exposures to COPCs in Soil or Fringe Surface Sediment

The following equations were used to calculate the estimated exposures to COPCs in soil or fringe surface sediment (USEPA, 1989a, 2004a).

Intake (lifetime and chronic) following incidental ingestion of soil or sediment (mg/kg-day):

$$Intake = \frac{CS\ x\ IR_S\ x\ FI\ x\ EF\ x\ ED\ x\ AAF_o\ x\ CF}{BW\ x\ AT}$$

where:

Intake	=	intake (mg/kg-day)
CS	=	soil/fringe surface sediment concentration (mg/kg – dry weight)

IR_s	=	ingestion rate of fringe surface soil/sediment (mg/day)
FI	=	fraction ingested from Study Area (unitless)
EF	=	exposure frequency (days/year)
ED	=	exposure duration (year)
AAF_o	=	oral absorption adjustment factor (chemical-specific) (unitless)[15]
CF	=	unit conversion factor (kg/10^6 mg)
BW	=	body weight (kilograms)
AT	=	averaging time (days)

Intake (lifetime and chronic) following dermal contact with soil or fringe surface sediment (mg/kg-day):

$$Intake = \frac{CS\ x\ SA\ x\ AF\ x\ EF\ x\ ED\ x\ DAF\ x\ CF}{BW\ x\ AT}$$

where:

Intake	=	intake (mg/kg-day)
CS	=	soil/fringe surface sediment concentration (mg/kg – dry weight)
SA	=	exposed skin surface area (cm^2/day)
AF	=	skin adherence factor (mg /cm^2)
EF	=	exposure frequency (days/year)
ED	=	exposure duration (year)
DAF	=	dermal absorption fraction (chemical-specific) (unitless)
CF	=	unit conversion factor (kg /10^6 mg)
BW	=	body weight (kilograms)
AT	=	averaging time (days)

5.2.2 Estimating Potential Exposures to COPCs in Air

The following equation is used to calculate the estimated exposure from COPCs in outdoor air, excavation trench air, or indoor air.

Average daily exposure (lifetime and chronic) following inhalation of COPC (mg/m^3):

$$ADE = \frac{CA\ x\ ET\ x\ EF\ x\ ED}{AT}$$

where:

ADE	=	average daily exposure (mg/m^3)

[15] The term AAF is synonymous with the term Relative Bioavailability Factor (RBA).

CA	=	air concentration (mg/m^3)
ET	=	exposure time (hours/day)
EF	=	exposure frequency (days/year)
ED	=	exposure duration (year)
AT	=	averaging time (hours)

5.2.3 Estimating Potential Exposures to COPCs in Surface Water

The following equations were used to calculate the estimated exposures to COPCs in surface water (USEPA 1989a, 2004a).

Intake (lifetime and chronic) following incidental ingestion of surface water (mg/kg-day):

$$Intake = \frac{CW\ x\ IR_W\ x\ ET\ x\ EF\ x\ ED}{BW\ x\ AT}$$

where:

Intake	=	intake (mg/kg-day)
CW	=	water concentration (mg/L)
IR_W	=	ingestion rate of water (L/hour)
ET	=	exposure time (hours/day)
EF	=	exposure frequency (days/year)
ED	=	exposure duration (year)
BW	=	body weight (kilograms)
AT	=	averaging time (days)

Calculation of the dose from dermal exposure to surface water follows USEPA guidance (2004a), which differentiates between organic and inorganic chemicals, as presented below. The following equations are used to estimate the dermally absorbed dose following dermal contact with surface water.

Dermally absorbed dose (lifetime and chronic) following dermal contact with surface water (mg/kg-day):

$$DAD = \frac{DA_{event}EF\ x\ EV\ x\ ED\ x\ SA}{BW\ x\ AT}$$

where:

DAD	=	dermally absorbed dose (mg/kg-day)
DA_{event}	=	absorbed dose per event (mg/cm^2-event)
EF	=	exposure frequency (days/year)
EV	=	event frequency (1 event/day)

ED	=	exposure duration (years)
SA	=	body surface area (cm^2)
BW	=	body weight (kilograms)
AT	=	averaging time (days)

The calculation of the dose absorbed per unit area per event (DA_{event}) for inorganics or highly ionized organics is as follows:

$$DA_{event} = K_p \ x \ CW \ x \ ET \ x \ CF$$

where:

DA_{event}	=	absorbed dose per event (mg/cm^2-event)
CW	=	concentration in water (mg/L)
K_p	=	permeability constant (cm/hour)
ET	=	exposure time (hours/event)
CF	=	conversion factor (L/1000 cm^3)

The calculation of DA_{event} for organics is as follows:

If ET < t*, then:

$$DA_{event} = 2FA \ x \ K_p \ x \ CW \ x \ CF \sqrt{\frac{6T \ x \ ET}{\pi}}$$

If ET > t*, then:

$$DA_{event} = FA \ x \ K_p \ x \ CW \ x \ CF \ x \left[\frac{ET}{1+B} + 2T\left(\frac{1+3B+3B^2}{(1+B^2)}\right)\right]$$

where:

t*	=	time to steady state (hour)
DA_{event}	=	absorbed dose per event (mg/cm^2-event)
FA	=	fraction absorbed water (dimensionless)
K_p	=	permeability constant (cm/hour)
CW	=	concentration in water (mg/L)
CF	=	conversion factor (L/1000 cm^3)
T	=	lag time per event (hours/event)
ET	=	exposure time (hours/event)

B = dimensionless ratio of the K_p of a chemical through the stratum corneum relative to its K_p across the viable epidermis

5.2.4 Estimating Potential Exposures to COPCs in Fish Tissue

The following equation is used to calculate the estimated exposures to COPCs via fish consumption (USEPA, 1989a).

Intake (lifetime and chronic) following fish consumption (mg/kg-day):

$$Intake = \frac{Cf \ x \ FCR \ x \ FI \ x \ (1 - Loss) x \ EF \ x \ ED}{AT \ x \ BW}$$

where:

Intake	=	intake (mg/kg-day)
Cf	=	concentration in fish tissue (mg/kg - wet weight)
FCR	=	fish consumption rate (kg/day)
FI	=	fraction ingested from Study Area
Loss	=	preparation/cooking loss (unitless)
EF	=	exposure frequency (days/year)
ED	=	exposure duration (years)
BW	=	body weight (kilograms)
AT	=	averaging time (days)

5.3 Receptor-Specific Exposure Parameters

This section identifies the receptor-specific exposure parameters that were used to estimate exposure doses for the potential receptors in the BHHRA. As described in the Risk Assessment Work Plan, both RME and CTE scenarios were evaluated. The CTE uses average exposure parameters to calculate an average exposure to an individual. The RME provides an estimate of the upper range of exposure in a population (the 90th percentile or greater of expected exposure, consistent with USEPA, 1992b) and is based on a combination of the upper-bound and central estimates of exposure parameters. As stated in the RAGS Part A (USEPA, 1989a):

> *Actions at Superfund sites should be based on an estimate of the RME expected to occur under both current and future land-use conditions. The reasonable maximum exposure is defined here as the highest exposure that is reasonably expected to occur at a site. RMEs are estimated for individual pathways.*

It is not appropriate to set all RME exposure factor inputs to upper-percentile values, inasmuch as the resulting exposure estimates may exceed RMEs for the population of interest (USEPA, 2004b). The intent of the RME is to estimate a conservative exposure case that is above the average case but still within the range of possible exposures (USEPA, 1989b, 1992b). The purpose of evaluating both CTE and RME scenarios in the BHHRA is to provide risk managers and stakeholders with an estimate of the range of risks from average to upper-bound.

There are a number of parameters for which site-specific data are critical, and use of default exposure assumptions, such as those provided in USEPA risk assessment guidance documents (USEPA, 1989a, 2011, 2014a), may overestimate or underestimate site-specific conditions. For example, recreational exposures at a river depend on factors such as water quality, land and waterway use, public access, and fishery characteristics, as well as demographics of the population. For parameters such as fish consumption rate, exposure frequency, and the duration of exposure events, use of site-specific information promotes development of exposure parameter values that are realistic. For the Benning Road BHHRA, local fish consumption studies, water quality and fishery information, land use and recreation information, and demographic data were considered.

Tables 5-2, 5-3, 5-4, 5-5, and **5-6** present the exposure parameter values used to quantitatively estimate potential risks from exposures to soil, excavation trench air, fringe surface sediment, surface water, and fish tissue, respectively. Exposure factors used in the screening level evaluation of the vapor intrusion to indoor air pathway are those recommended in USEPA (2014a). In accordance with guidance (USEPA, 1989a), the assumptions are intended to capture exposures under both current and future Study Area conditions. The conceptual site model was developed taking into consideration the existing parks, walking trails, boat docks, and fishing activity within the Waterside Investigation Area, as well as potential improvements to these resources. However, it is possible that recreational use could increase at a level higher than assumed here. Therefore, a discussion of the potential for increased exposure in the future is provided in the uncertainty analysis (Section 7). Uncertainties associated with the selected exposure parameters are also discussed in the uncertainty analysis.

A description of each Landside receptor evaluated in the BHHRA is provided in Section 5.3.1 and of each Waterside receptor in Section 5.3.2. The technical basis for the following exposure parameters used in the BHHRA is discussed in **Attachment C**:

- Fish Consumption Exposure Parameters
- Fringe Surface Sediment Ingestion Rates
- Surface Water Ingestion Rates
- Body Surface Areas Exposed
- Skin Adherence Factors
- Exposure Frequency
- Exposure Duration
- Body Weight

5.3.1 Landside Receptors

Landside receptors are assumed to be potentially exposed to soil and groundwater and include potential future recreational visitors and workers.

5.3.1.1 Current/Future Construction Worker

It is assumed that current and future construction workers performing subsurface excavations for utility repair or other construction work may be exposed to COPCs via the following pathways:

- Direct contact (incidental ingestion and dermal contact) with soil (surface and subsurface)
- Inhalation of particulates derived from soil in outdoor air (no volatile COPCs were identified in soil)
- Inhalation of vapors from groundwater in an excavation trench

5.3.1.2 Future Outdoor Industrial Worker

It is assumed that the future outdoor industrial worker may be exposed to COPCs in surface soil via the following pathways:

- Direct contact (incidental ingestion and dermal contact) with surface soil
- Inhalation of particulates derived from surface soil in outdoor air (no volatile COPCs were identified in soil)

5.3.1.3 Future Indoor Industrial Worker

It is assumed that the future indoor industrial worker may be exposed via inhalation to volatile COPCs resulting from groundwater vapor intrusion to indoor air.

5.3.1.4 Future Recreational Visitor

It is assumed that the future recreational visitor (older child/teen, age 7 to <19) may be exposed to COPCs in surface soil in via the following pathways:

- Direct contact (incidental ingestion and dermal contact) with surface soil
- Inhalation of particulates derived from surface soil in outdoor air (no volatile COPCs were identified in soil)

5.3.2 Waterside Receptors

Waterside receptors are assumed to be potentially exposed to Anacostia River media adjacent to the Site (fringe surface sediment, surface water, and fish tissue). Both recreational and worker receptors were considered, as described below.

5.3.2.1 Angler

Angler receptors are defined as those individuals who consume self-caught fish from the Anacostia River in spite of the consumption advisories. Adults and older children/teenagers (7 to <19 years old) are assumed to fish in the Waterside Investigation Area and consume their catch. These anglers are assumed to share self-caught fish with other members of their household.

Anglers can fish from various locations along the shoreline, including parks, bulkheads, bridges, boat launches, and docks, as well as from boats. Anglers are not expected to contact surface water or fringe surface sediment on days when they fish from bridges or bulkheads. However, on days when anglers fish from areas such as mudflats or accessible shoreline, they may be exposed to COPCs in fringe surface sediment and surface water.

A number of parameters were used to calculate the potential risk from consumption of fish, including consumption rate, species, tissue type consumed, fraction ingested from the Waterside Investigation Area, preparation and cooking methods, and years of fishing at the Site. In selecting appropriate fish consumption exposure parameters, USEPA guidance (USEPA, 1989a, b, 1998, 2000, 2011) discusses the importance of considering site-specific factors, including water quality, public access, abundance of desirable species, and proximity of other desirable water bodies, as well as characteristics of the angling population.

The Anacostia River is a tidal river with habitat suitable for a variety of freshwater and estuarine species, including American eel, brown bullhead, channel catfish, largemouth and smallmouth bass, carp, and sunfish. Angling has been observed from shore and boat. A water body-specific fish consumption advisory is in effect for the Anacostia and Potomac Rivers recommending against consumption of some species (catfish, carp, and American eel) and limited consumption of other species (e.g., largemouth bass and sunfish) due to PCBs and pesticides (DOEE, 2016a). However, some people may not be aware of the advisory, or may choose to catch and eat river fish despite the presence of the advisory.

To aid in the development of appropriate fish consumption exposure parameters, available local and regional angler studies were consulted. The fish consumption rate and fraction ingested exposure parameters used in the BHHRA are discussed in **Attachment D**. Cooking loss factors, which are chemical-specific parameters, are discussed in Section 5.4.4.

It is assumed that the current/future angler receptor may be exposed to COPCs via:

- Consumption of fish caught in the Anacostia River within the Waterside Investigation Area
- Direct contact (incidental ingestion and dermal contact) with fringe surface sediment in the Waterside Investigation Area
- Direct contact (incidental ingestion and dermal contact) with River surface water in the Waterside Investigation Area

5.3.2.2 Swimmer

Recreational users of the Anacostia River may occasionally swim in the River within the Waterside Investigation Area, although this is expected to be an infrequent activity. The swimmer receptor includes the young child (1 to <7 years), older child/teen (7 to <19 years), and adults (>18 years). Given visible deterrents, including the presence of trash and debris along the shoreline and floating in the water, the generally urban setting, including combined sewer overflows and lack of designated swimming spots along the River, as well as pathogen loadings,[16] the frequency and duration of swimming is expected to be low under both current and future conditions.

It is assumed that the current/future swimmer may be exposed to COPCs via:

- Direct contact (i.e., incidental ingestion and dermal contact) with fringe surface sediment within the Waterside Investigation Area
- Direct contact (i.e., incidental ingestion and dermal contact) with River surface water within the Waterside Investigation Area

5.3.2.3 Wader

Recreational users of the Anacostia River may occasionally wade along the River's edge in the Waterside Investigation Area. This includes individuals who may boat and contact fringe surface sediment and surface water while entering and exiting their boat (e.g., canoe, kayak, scull), as well as a variety of other activities, such as general play, dog walking, bird watching, etc. Waders include the young child (1 to <7 years), older child/teen (7 to <19 years), and adults (>18 years).

[16] The presence of high levels of pathogens in the Anacostia is the primary reason the River is not considered safe for swimming (DOEE, 2008, 2014b).

It is assumed that the current/future wader may be exposed to COPCs via:

- Direct contact (incidental ingestion and dermal contact) with fringe surface sediment within the Waterside Investigation Area
- Direct contact (incidental ingestion and dermal contact) with River surface water within the Waterside Investigation Area

5.3.2.4 Shoreline Worker

Workers, including NPS employees, may perform outdoor activities such as trash collection, shoreline maintenance, or other activities that bring them into contact with fringe surface sediment and surface water along the edge of the River adjacent to the Waterside Investigation Area. The worker receptor is assumed to be an adult. It is assumed that the current/future worker may be exposed to COPCs via:

- Direct contact (incidental ingestion and dermal contact) with fringe surface sediment within the Waterside Investigation Area
- Direct contact (incidental ingestion and dermal contact) with River surface water within the Waterside Investigation Area

5.4 Chemical-Specific Parameters

The chemical-specific dermal and oral absorption, dermal water absorption, and preparation/cooking loss parameters identified in the equations presented in Section 5.2 are described below.

5.4.1 Dermal Absorption Fractions

The dermal absorption fraction (DAF) accounts for lower absorption through the skin. USEPA chemical-specific DAFs were used where available (USEPA, 2004a). The DAFs for COPCs in soil and fringe surface sediment were compiled from RAGS Part E (USEPA, 2004a) and are presented in **Table 5-7**.

5.4.2 Oral Absorption Adjustment Factors

Absorption adjustment factors (AAFs), or relative bioavailability factors (RBAs), are used in risk assessment to account for absorption differences between humans exposed to substances in environmental situations and experimental animals in the laboratory studies used to derive dose-response values. Support for use of AAFs is provided in USEPA guidance (1989a, 1992b). The AAF is the ratio between the estimated human absorption factor for the specific medium and route of exposure, and the known or estimated absorption factor for the laboratory study from which the dose-response value was derived.

AAF = (fraction absorbed in humans for the environmental exposure) / (fraction absorbed in the dose-response study)

The use of an AAF allows the risk assessor to make appropriate adjustments if the efficiency of absorption between environmental exposure and experimental exposure is known or expected to differ because of physiological effects and/or matrix or vehicle effects. When the dose-response curve is based on administered dose data, and if it is estimated that the fraction absorbed from the site-specific exposure is the same as the fraction absorbed in the laboratory study, then the AAF is 1. In the absence of detailed toxicological information on every chemical, it has been common practice for risk assessors to use a default oral AAF value of 1. However, use of AAFs in standard risk assessment calculations can provide more accurate and more realistic estimates of potential human health risk.

For all soil and fringe surface sediment COPCs except arsenic, a conservative default oral AAF value of 1 was used, which is consistent with the approach used by USEPA in the derivation of RSLs (USEPA, 2018a). For arsenic, USEPA's default oral AAF/RBA of 0.6 was used, which is also consistent with the derivation of soil RSLs (USEPA, 2012, 2018a). The default oral AAFs are presented in **Table 5-7**. The uncertainty associated with using default absorption factors is discussed in the uncertainty analysis.

5.4.3 Dermal Water Parameters

The estimation of exposure resulting from incidental dermal contact with surface water requires the use of a dermal permeability constant (K_p) in units of centimeters per hour (cm/hr). This method assumes that the behavior of chemicals dissolved in water is described by Fick's Law. In Fick's Law, the steady-state flux of the solute across the skin (in milligrams per square centimeter per hour [$mg/cm^2/hr$]) equals the permeability constant (K_p, cm/hr) multiplied by the concentration difference of the solute across the membrane (in milligrams per cubic centimeter [mg/cm^3]). This approach is discussed by USEPA (USEPA, 1989b, 2004a).

The K_p values were obtained from USEPA (2004a) Exhibit B-3. In addition to the K_p, several other parameters are necessary to calculate dermal dose from exposure to organic chemicals in water. These parameters, also obtained from USEPA (2004a) Exhibit B-3, include the ratio of the permeability coefficient of a chemical through the stratum corneum relative to its permeability coefficient across the viable epidermis (B, dimensionless), lag time (τ, hours/event), and time to steady state (t*, hours).[17]

[17] The spreadsheets that accompany RAGS Part E (USEPA, 2004a) (available on USEPA's website https://www.epa.gov/risk/risk-assessment-guidance-superfund-rags-part-e) were used to obtain the specific numerical values for the dermal water dose parameters, as the printed version shows 0.0 for small values.

Consistent with USEPA guidance (2004a, 2018a), dermal contact with surface water was not evaluated for COPCs that are outside the effective predictive domain of the regression model used to derive K_p values, including 2,3,7,8-TCDD-TEQ, 4,4-DDT, and PCBs. These COPCs are discussed qualitatively in the uncertainty analysis.

Table 5-8 presents the dermal water parameters used in the BHHRA.

5.4.4 Preparation/Cooking Loss

Preparation and cooking procedures can modify the amount of COPC ingested by fish consumers (USEPA, 2000). Numerous studies have demonstrated the loss of chemicals such as PCBs and other organic chemicals from fish tissues during preparation and cooking (e.g., Bayen et al., 2005; Hori et al., 2005; Moya et al., 1998; Schecter et al., 1998; Zabik et al., 1994, 1995a, 1995b, 1996; Skea et al., 1979). Cooking loss factors have been included in HHRAs for several sediment sites, including the Housatonic River (Weston, 2005), Lower Fox River (RETEC, 2002), and Kalamazoo River (CDM, 2003). In addition, a preparation and cooking loss factor of 50% for PCBs is used in the derivation of consumption advisories for the Great Lakes (Protocol for a Uniform Great Lakes Sport Fish Consumption Advisory, GLFATF, 1993).

While there is variability and uncertainty in the amount of chemical that is lost during preparation and cooking, the default assumption that no chemical is lost is overly conservative. An assumption of 0% loss represents consumption of a raw, untrimmed fish, since even consuming the cooking juices is unlikely to result in 100% of all of the chemical lost. Consistent with the intent of using an upper-bound (e.g., 90th percentile) value for the RME scenario, a lower 10th percentile on the range of cooking loss factors represents an RME estimate for cooking loss. **Attachment D** presents the calculation of selected percentiles of cooking loss factors for COPCs in fish tissue based on a review of the literature. As shown in **Table 5-9**, the 10th percentile values were used for the RME scenario, and median values were used for the CTE scenario. **Attachment D** presents the derivation of the cooking loss values.

5.5 Exposure Point Concentrations

Exposure points are located where potential receptors may contact COPCs at or from the Study Area. The concentration of COPCs in the environmental medium that receptors may contact must be estimated in order to determine the magnitude of potential exposure. The estimation of EPCs in media evaluated in this BHHRA is discussed below. Both measured and modeled EPCs are discussed where applicable.

5.5.1 Measured EPCs

Per the approved Risk Assessment Work Plans (AECOM, 2012, 2016d), the EPC is defined as the 95% upper confidence limit on the mean (UCL) (USEPA, 2002b) for the RME scenario, and the mean for the CTE scenario.[18]

UCLs were calculated using USEPA's ProUCL software (ProUCL Version 5.1, USEPA, 2016). Reporting limits for non-detected data were entered into ProUCL at the full reporting limit. ProUCL identifies the appropriate method with which to estimate the concentrations of the non-detect results rather than simply substituting a value such as the detection limit or one-half the detection limit. The UCL recommended by ProUCL was selected as the EPC, unless the recommended UCL was based on the H-statistic[19] or exceeded the maximum detected concentration, in which case an alternate UCL was selected (USEPA, 2002b).

Based on information presented in the ProUCL guidance (USEPA, 2015) regarding minimum sample size and frequency of detection, UCLs were calculated when at least 10 samples and at least six detected results were available. While ProUCL version 5.1 recommends a minimum of 10 samples with six detected values to calculate reliable UCLs, the guidance recognizes that this may not always be possible due to resource or other restraints and allows the user best professional judgment when determining the validity of the calculations. Due to the small size of the fish tissue data sets for the tidal Anacostia River and the Potomac River, UCLs were calculated when at least four detected results were available. For the other data sets, UCLs were calculated when at least 10 samples and six detected results were available.

The input to and the output from the ProUCL program are presented in **Attachment E**.

Soil and Groundwater

Exposure areas are the discrete areas over which a specific exposure pattern is expected to occur over the duration of exposure. As noted in Section 5.1.1, eight exposure areas were defined for soil and groundwater. EPCs are presented in the following tables:

---

[18] The mean of detected concentrations was used when frequency of detection (FOD) was 100%, and the Kaplan Meyer mean (which includes non-detects) was used when the FOD was less than 100%. When the Kaplan-Meier mean could not be calculated due to an insufficient number of detections, then the arithmetic mean of the detected results was selected.

[19] ProUCL computes and outputs UCLs based on the H-statistic for historical reasons only, and notes in the output that "the H-statistic often results in unstable (both high and low) values of UCL95" (USEPA, 2015). Further, the guidance states that "it is therefore recommended to avoid the use of H-statistic based 95% UCLs," and recommends use of non-parametric statistics.

- Surface soil – **Table 5-10** (RME) and **5-11** (CTE)
- Soil (0 to 16 feet bgs) – **Table 5-12** (RME) and **5-13** (CTE)
- Groundwater (UWZ) – **Table 5-14** (RME) and **5-15** (CTE)

Fringe Surface Sediment

The Waterside Investigation Area was evaluated as one exposure area for fringe surface sediment. **Tables 5-16** and **5-17** present the RME and CTE fringe surface sediment EPCs, respectively.

Surface Water

As described in Section 3.1.4.2 and depicted in **Figure 3-5**, 10 surface water samples were collected in the Waterside Investigation Area. Because river water is continuously moving, all of the Waterside Investigation Area samples were included in the calculation of the surface water EPCs. **Tables 5-18** and **5-19** present the RME and CTE surface water EPCs, respectively.

Fish Tissue

Anglers' species preferences, species abundance, and feeding guilds were considered in developing tissue EPCs. Based on the angler surveys, the species that is most preferred for consumption is catfish (Gibson and McClafferty, 2005; OpinionWorks, 2012). Catfish have historically been abundant in the DC area waters (MDNR, 2016). In addition to catfish, other species have been reported to be consumed by local anglers, including largemouth bass, striped bass, bullhead, sunfish, and occasionally carp. Thus, the BHHRA evaluated a mixed fish diet scenario that assumed consumption of multiple species representing various feeding guilds and habitats based on angler preferences and available tissue data for each River reach evaluated. This species mix included bottom feeders (carp, catfish, eel), predators (largemouth bass), sunfish, and northern snakehead. Little consumption of carp and eel was reported by anglers (Gibson and McClafferty, 2005). Thus, including these bottom-dwelling species, which generally have high tissue concentrations of lipophilic chemicals including PCBs, results in a conservative mixed fish EPC for the BHHRA. The uncertainty analysis provides an evaluation of a catfish only diet.

EPCs were calculated for each of the five river reaches identified in Section 3.1.4.3 and shown in **Figures 3-7** to **3-9**:

- Upper Anacostia River Area (upstream of the CSX bridge); includes the Waterside Investigation Area, and extends approximately 1.3 miles downstream and 1.9 miles upstream of the Benning Road bridge;
- Lower Anacostia River Area (downstream of the CSX bridge);

- Lower Potomac River (downstream of the 14th Street bridge);
- Upper Potomac River (upstream of the 14th Street bridge);
- Upstream Non-Tidal Anacostia River (north of the Maryland state line); upstream of the Waterside Investigation Area; background area

Tables 5-20 and **5-21** present the RME and CTE fish tissue EPCs, respectively. Mixed diet EPCs were calculated using the available fish species in each reach. Alternative fish diets are evaluated in the uncertainty analysis, as well as consumption of other biota. The available data suggest that crabbing and crab consumption is limited in the Anacostia River. Only six of the 247 DC area anglers interviewed during the 2004 survey reported consuming crab (Gibson and McClafferty, 2005). In addition, blue crabs are not typically present in the Anacostia River (NOAA, 2012).

5.5.2 Modeled EPCs

Fugitive Dust

EPCs for COPCs in fugitive dust (outdoor air) were predicted by combining soil EPCs (calculated as discussed in Section 5.5.1) with particulate emission factors (PEFs) calculated in accordance with USEPA guidance (2002c). PEFs were conservatively calculated based on the total size of the Site (77 acres).

The PEF of 5.7×10^8 cubic meters per kilogram (m^3/kg) for outdoor industrial workers and recreational visitors (see **Table 5-22**) was calculated in accordance with USEPA guidance (2002c) using default inputs for a wind-driven/non-excavation scenario and climate inputs representative of Philadelphia, which is the closest city with data available from USEPA (2002c, Exhibit 5-2). The PEF of 8.2×10^5 m^3/kg for construction workers (see **Table 5-23**) was calculated using default inputs for an unpaved road traffic scenario (USEPA 2002c, Exhibit 5-2). The PEF model takes into account the number of days per year with precipitation of at least 0.01 inches. Based on information from the University of North Carolina, Southeast Regional Climate Center,[20] the annual average number of days per year with at least 0.01 inches of precipitation, measured at the Ronald Reagan Washington National Airport in Washington, DC, is 107 days.

Outdoor air EPCs for the non-excavation scenarios are presented in **Tables 5-24** (RME) and **5-25** (CTE). Outdoor air EPCs for the excavation scenario are presented in **Tables 5-26** (RME) and **5-27** (CTE).

Groundwater Volatilization to Air

Excavation trench air concentrations of COPCs resulting from volatilization from groundwater infiltrating an excavation trench were modeled using a Virginia Department of Environmental Quality (VDEQ) model (VDEQ, 2018). The model for groundwater less than 15 feet bgs was used, with modifications, as discussed in **Attachment F**. The trench air concentrations were used to evaluate the current/future construction worker receptor. Trench air EPCs are presented in **Tables 5-28** (RME) and **5-29** (CTE).

Estimated concentrations of COPCs in indoor air under a potential future vapor intrusion evaluation were estimated using USEPA's VISL calculator in **Attachment B**.

5.6 Groundwater-to-Surface Water Evaluation

Groundwater in the area of the Site discharges to the adjacent Anacostia River. The BHHRA included an evaluation of the potential impact of Site groundwater on the River by comparing estimated in-stream concentrations of chemicals entering the river via groundwater flow from the Site to applicable surface water screening levels. Six nearshore monitoring wells located at the downgradient edge of the Site (MW-01, MW-02, MW-03, MW-04, MW-08, and MW-11) were used to estimate potential Site-related chemicals in groundwater that may be migrating to the River. As discussed in the RI Report, the wells further from the River are not expected to contribute significantly to the potential migration to surface water pathway. The calculation of in-stream concentrations of groundwater chemicals and comparison to surface water screening levels is described below.

5.6.1 Dilution Attenuation Factor Calculation

Groundwater discharges from the Site to the River were calculated for the UWZ and LWZ at the six pairs of nested waterfront wells, from which dilution attenuation factors were computed. Groundwater flux was computed using Darcy's Law: Q = KIA, where "Q" is discharge in cubic feet per second (ft^3/sec), "K" is hydraulic conductivity in feet per second (ft/sec), "I" is hydraulic gradient (unitless), and "A" is the area through which the groundwater flows in square feet (ft^2). For waterfront wells in which aquifer testing was conducted during the RI (MW-01, MW-03, and MW-11), the average calculated K value was used for the wells' hydraulic conductivity. For wells in which aquifer testing was not conducted, the geometric mean of hydraulic conductivities from the three nearest aquifer-tested wells was used. A local hydraulic gradient was calculated for each well using the slope of the plane formed by the low-tide groundwater level in the well and the groundwater levels in two upgradient wells (three-point problem approach using USEPA's online tool, USEPA, 2018f). A unique cross-sectional area was computed for each well based on water-bearing zone thickness at the well (upper or lower) and a length of boundary segment through which groundwater flows to the River.

The dilution attenuation factors were calculated by dividing the groundwater discharges for each waterfront well by the 7-day, 10-year low streamflow (7Q10) of the River adjacent to the Site (13.9 ft^3/sec), estimated using the United States Geological Survey (USGS) Maryland StreamStats application, an online GIS tool for estimating stream flows at ungauged locations (USGS, 2018). The 7Q10 is the lowest 7-day average streamflow that occurs on average once every 10 years.

5.6.2 Instream Surface Water Concentration Calculation

The instream concentrations for each chemical detected in the waterfront wells was calculated by multiplying the groundwater concentrations by the corresponding dilution attenuation factor. The nearshore wells were sampled in November 2014, and samples were analyzed for dioxins and furans, metals, pesticides, PCBs, SVOCs, and VOCs. As discussed in the Risk Assessment Work Plan Addendum (AECOM, 2016d), a number of the elevated constituent concentrations detected during the initial sampling, including dioxins and furans, were attributed to turbidity in the groundwater samples. The turbidity was suspected to be due in part to inadequate well development at the time of monitoring well installation. Therefore, the wells were re-developed and resampled using low-flow methods. The 2016 samples were analyzed for a sub-set of the chemicals analyzed in 2014 and varied by well. For the nearshore wells included in the groundwater to surface water evaluation, the following were analyzed in 2016:[21]

- MW-01A: PAHs, dioxins and furans, VOCs
- MW-01B: PAHs, VOCs
- MW-02A: PAHs, VOCs
- MW-02B: PAHs
- MW-03A/B: no analysis relevant to BHHRA
- MW-04A: dioxins and furans
- MW-04B: pesticides
- MW-08A: no analysis relevant to BHHRA
- MW-08B: pesticides
- MW-11A: dioxins and furans, pesticides, VOCs
- MW-11B: dioxins and furans, VOCs

To provide a complete analysis of the potential for groundwater discharge to surface water, the most recent data point for each well and chemical was used to estimate in-stream concentrations.

Table 5-30 presents the groundwater concentrations and estimated instream concentrations for each of the waterfront wells. The dilution attenuation factor calculations are provided in **Attachment G**.

[21] Only analysis methods used in the BHHRA are listed; for example, PCB congeners, PAHs via method ID-0016, and forensics parameters are not included.

5.6.3 Comparison to Surface Water Screening Levels

The same groundwater-to-surface water screening levels used for COPC selection were also used in the surface water evaluation (see Section 3.2.2). The DOEE water quality standards and USEPA national recommended water quality criteria are based on protection of fish and shellfish that may be consumed by humans. As previously noted, these criteria are typically derived by relating acceptable risk-based concentrations in fish tissue to concentrations in surface water via a BAF. Therefore, they are appropriate screening levels for evaluating the potential impact of Site groundwater on the Anacostia River.

As shown in **Table 5-30**, none of the estimated in-stream concentrations of chemicals in either the UWZ or LWZ exceed their respective surface water screening levels. In summary, based on the results of this screening-level evaluation, Site groundwater is not adversely impacting the Anacostia River.

6 Risk Characterization

The potential risk to human health associated with exposure to COPCs in environmental media at the Study Area was evaluated in the risk characterization step of the risk assessment process. Risk characterization is the process in which the dose-response information (Section 4) is integrated with quantitative estimates of human exposure derived in the Exposure Assessment (Section 5). The result is a quantitative estimate of the likelihood that humans will experience any adverse health effects given the exposure assumptions made. Two general types of health risk are characterized for each potential exposure pathway considered: potential carcinogenic risk and potential noncarcinogenic hazard. Potential carcinogenic risk is evaluated by averaging exposure over a normal human lifetime, which, based on USEPA guidance (1989a), is assumed to be 70 years.[22] Potential noncarcinogenic hazard is evaluated by averaging exposure over the total exposure period.

Characterization of the potential health effects of potential carcinogenic and noncarcinogenic chemicals is approached in very different ways. The difference in approaches arises from the conservative assumption that substances with possible carcinogenic action proceed by a no-threshold mechanism, whereas other toxic actions may have a threshold, i.e., a dose below which few individuals would be expected to respond. Thus, under the no-threshold assumption, it is necessary to calculate a risk, but for chemicals with a threshold, it is possible to simply characterize an exposure as above or below the threshold. In risk assessment, that threshold is termed a reference dose or reference concentration. Reference doses and cancer slope factors were discussed in Section 4. The approach to carcinogenic risk characterization is presented in Section 6.1, and the approach to noncarcinogenic risk characterization is presented in Section 6.2. The risk characterization results are presented in Section 6.3. Potential carcinogenic risks and noncarcinogenic hazard indices are presented in the text and tables using one significant figure.[23] Section 6.4 discusses potential chemicals of concern (COCs), and Section 6.5 addresses background conditions in relation to risk. The risk calculations are presented in **Attachment H** and summarized in tables in this section.

---

22 More up-to-date "lifetimes" of 75 years (males), 80 years (females), and 78 years (males and females) are provided in the USEPA's updated Exposure Factors Handbook (2011), which would lower cancer risk estimates by approximately 7% (males only), 13% (females only), and 10% (males and females combined). However, USEPA (2014a) has retained the default of 70 years pending additional evaluation by NCEA.

23 Based on standard practice for number rounding, risk estimates for which the first digit after the decimal place was equal to or greater than 5 were rounded up (e.g., 1.5 x 10^{-4} rounds to 2 x 10^{-4}), and risk estimates for which the digit after the decimal place was less than 5 were rounded down (e.g., a hazard index of 1.4 rounds to 1).

6.1 Carcinogenic Risk Characterization

The purpose of carcinogenic risk characterization is to estimate the upper-bound likelihood that a human receptor will develop cancer in his or her lifetime as a result of exposure to a chemical in an environmental medium. This likelihood is a function of the dose of a chemical (described in the Exposure Assessment) and the CSF (described in the Dose-Response Assessment) for that chemical.

The American Cancer Society (ACS) estimates that the lifetime probability of contracting cancer in the U.S. is 1 in 3 based on data from 2012 to 2014 (ACS, 2018). The Excess Lifetime Cancer Risk (ELCR) associated with estimated exposures at a site is the likelihood, over and above the lifetime probability, that an individual will develop cancer in his or her lifetime due to those site exposures. The cancer risk is expressed as a probability (e.g., 10^{-6}, or 1 in one million). An ELCR of 10^{-6} indicates that an individual would have a 1 in one million chance of developing cancer in addition to the 1 in 3 chance estimated by the ACS. The relationship between the ELCR and the estimated lifetime average daily dose (LADD) or average daily exposure (ADE) of a chemical may be expressed as:

$$ELCR = 1\text{-}e^{-(CSF \text{ x } LADD \text{ or } ADE)}$$

If the product of the CSF and the LADD is much greater than 1, the ELCR approaches 1 (i.e., 100 percent probability). If the product is less than 0.01 (1 chance in 100), the equation can be closely approximated by:

- Oral/Dermal: ELCR = LADD (mg/kg-day) x CSF $(\text{mg/kg-day})^{-1}$
- ELCR = Lifetime ADE (mg/m^3) x URF $(\mu\text{g/mg}^3)^{-1}$ x 1,000 µg/mg

The product of the CSF/URF and the LADD/ADE is unitless and provides an upper-bound estimate of the potential carcinogenic risk associated with a receptor's exposure to a chemical or an exposure pathway for each receptor. Current USEPA risk assessment guidelines assume that cancer risks are additive or cumulative. Pathway- and area-specific risks are summed to estimate the total potential cancer risk for each receptor.

USEPA has established target risk levels under the National Contingency Plan (NCP) (USEPA, 1990). Target risk levels refer to levels of cancer risk or hazard indices that are deemed acceptable by the USEPA or other regulatory agencies. These are levels below which the potential for adverse effects to humans are assumed to be negligible or inconsequential. The NCP establishes a target cancer risk range of 10^{-6} to 10^{-4} and a target HI of less than or equal to 1 (USEPA, 1990). The USEPA subsequently clarified that, "Where the cumulative carcinogenic site risk to an individual based on reasonable maximum exposure for both current and future land use is less than 10^{-4}, and the non-carcinogenic hazard quotient is less than 1, action generally is not warranted, unless there are adverse environmental impacts" (USEPA, 1991). Potential COCs are identified in this BHHRA, per DOEE request, as those COPCs with individual cancer risks greater than 1 x 10^{-6}. The identified COCs are discussed and summarized in Section 6.4.

6.2 Noncarcinogenic Risk Characterization

The potential for adverse noncarcinogenic health effects is estimated for each receptor by comparing the chronic average daily dose (CADD) for each COPC with the RfD for that COPC. The resulting ratio, which is unitless, is known as the HQ for that chemical. The HQ is calculated using the following equations:

- Oral/dermal: HQ = CADD (mg/kg-day) ÷ RfD (mg/kg-day)
- Inhalation: HQ = ADE (mg/m^3) ÷ RfC (mg/m^3)

The target HQ is defined as an HQ of less than or equal to 1 (USEPA, 1989a). When the HQ is less than or equal to 1, the RfD or RfC has not been exceeded, and no adverse noncarcinogenic effects are expected. If the HQ is greater than 1, there may be a potential for adverse noncarcinogenic health effects to occur; however, the magnitude of the HQ cannot be directly equated to a probability or effect level.

The total HI is calculated for each exposure pathway by summing the HQs for each individual chemical. The total HI is calculated for each potential receptor by summing the HIs for each pathway associated with the receptor. If the total HI is greater than 1 for any receptor, a more detailed evaluation of potential noncarcinogenic effects based on specific target organs/health endpoints is performed (USEPA, 1989a).

A summary of all HIs for each receptor group is presented in this section and compared to the target HI of 1. The tables summarizing the per COPC HI show both the total HI and the highest HI by target endpoint; the tables presented in **Attachment H** also show the HI for each target endpoint. The summary tables embedded in the text of Section 6.3 present the highest target organ HI. Each COPC that has an HI above 1 for a particular receptor and for a particular target endpoint is designated a COC. If the cumulative target endpoint HIs for a receptor are less than 1, then no further evaluation or action is recommended to address potential noncarcinogenic hazards (carcinogenic risks must also be considered as discussed above). COPCs having a cumulative target endpoint HI for a receptor greater than 1 are also identified as COCs.

6.3 Risk Characterization Results

The results of the risk characterization are presented below for Landside receptors and Waterside receptors. The risk calculations, including the COPC-specific risks calculated for each receptor, medium, and exposure pathway, are presented in **Attachment H** for both the RME and CTE scenarios. **Attachment H** also presents the calculation of HI by target endpoint.

6.3.1 Landside Receptors

Risk characterization results for Landside receptors are presented below.

6.3.1.1 Current/Future Construction Worker

The construction worker receptor is assumed to be exposed to COPCs in soil via incidental ingestion and dermal contact, and via inhalation from particulates derived from soil as well as volatiles infiltrating an excavation trench from groundwater. The risk characterization results for the construction worker receptor are presented in **Tables 6-1** through **6-4** as follows:

- Table 6-1 Total Potential Carcinogenic Risks for Construction Worker Receptor, RME
- Table 6-2 Total Potential Hazard Index for Construction Worker Receptor, RME
- Table 6-3 Total Potential Carcinogenic Risks for Construction Worker Receptor, CTE
- Table 6-4 Total Potential Hazard Index for Construction Worker Receptor, CTE

As shown in **Tables 6-1** and **6-3**, the total potential carcinogenic risks are within or below the USEPA target risk range of 10^{-4} to 10^{-6} for the RME and CTE scenarios. As shown in **Tables 6-2** and **6-4**, total potential noncarcinogenic hazards are above the USEPA target HI of 1 for the RME scenario in the warehouse and laydown area, the salvage yard and waste storage space, and the transformer shop. While the total HI in the potential future park land/green space exceeds 1, target endpoint HIs do not exceed 1. Total HIs are below 1 under the CTE scenario. The cumulative RME and CTE cancer risks and noncancer hazards for the construction worker receptor are summarized in the following table.

Cumulative Risks/Hazards for Current/Future Construction Worker				
	Cancer		Noncancer [a]	
Exposure Area	**RME**	**CTE**	**RME**	**CTE**
Hypothetical Future Park Land/Green Space	2E-08	8E-09	1	0.3
Warehouse and Laydown Area	4E-07	7E-08	3	0.5
Salvage Yard and Waste Storage Area	5E-07	1E-07	0.7	0.1
Stores and Fleet Maintenance Area	9E-08	3E-08	0.2	0.07
Offices and Parking Lot	4E-07	8E-08	0.8	0.2
Substation #7	3E-07	3E-08	0.5	0.08
Transformer Shop	2E-06	7E-07	1.6	0.5
Vehicle Refueling Area	4E-08	1E-08	0.2	0.08

Notes:
Blue highlighting indicates that cumulative risk exceeds 10^{-6} but is less than or equal to 10^{-4}.
Yellow highlighting indicates that cumulative risk exceeds 10^{-4} or the target endpoint HI exceeds 1.
[a] Highest target endpoint HI.

The only COPC with a potential cancer risk greater than 10^{-6} is total PCBs under the RME scenario for the transformer shop, driven by direct-contact with soil.

As indicated in the risk calculation tables in **Attachment H**, target endpoint-specific HIs exceed 1 in two areas:

- Warehouse and laydown area. A target endpoint HI of 3 for respiratory effects from inhalation of particulates from soil was calculated for the warehouse and laydown area. The majority of the HI is due to inhalation of vanadium in soil fugitive dust. The RfC for vanadium is the ATSDR MRL for chronic exposure, which is defined as exposure durations greater than or equal to 1 year (a subchronic RfC for vanadium is not available). Therefore, the inhalation HI for vanadium is conservative and likely an overestimate of the potential hazard from short-term (40-day) inhalation exposure to soil during an excavation event in the warehouse and laydown area.
- Transformer shop. A target endpoint HI of 1.6 for eye, nails, and immune effects from ingestion and dermal contact with soil was calculated for the transformer shop, due to total PCBs. The HI for total PCBs is based on the subchronic RfD.

The target endpoint evaluation indicates that no other COPCs drive the exceedance of an HI of 1 on a target endpoint basis.

6.3.1.2 Future Outdoor Industrial Worker

The outdoor worker receptor is assumed to be exposed to COPCs in surface soil via incidental ingestion and dermal contact, and via inhalation from particulates derived from surface soil. The risk characterization results for the outdoor industrial worker receptor are presented in **Tables 6-5** through **6-8** as follows:

- Table 6-5 Total Potential Carcinogenic Risks for Outdoor Industrial Worker Receptor, RME
- Table 6-6 Total Potential Hazard Index for Outdoor Industrial Worker Receptor, RME
- Table 6-7 Total Potential Carcinogenic Risks for Outdoor Industrial Worker Receptor, CTE
- Table 6-8 Total Potential Hazard Index for Outdoor Industrial Worker Receptor, CTE

As shown in **Tables 6-5** and **6-7**, the total potential carcinogenic risks are within or below the USEPA target risk range of 10^{-4} to 10^{-6} for the RME and CTE scenarios with the exception of the transformer shop. As shown in **Tables 6-6** and **6-8**, the total potential noncarcinogenic hazards are below 1 with the exception of the transformer shop. The cumulative RME and CTE cancer risks and noncancer hazards for the outdoor industrial receptor are summarized in the following table.

Cumulative Risks/Hazards for Future Outdoor Industrial Worker				
	Cancer		**Noncancer [a]**	
Exposure Area	**RME**	**CTE**	**RME**	**CTE**
Hypothetical Future Park Land/Green Space	1E-06	1E-07	0.3	0.1
Warehouse and Laydown Area	2E-05	1E-06	1	0.2
Salvage Yard and Waste Storage Area	1E-05	1E-06	0.3	0.05
Stores and Fleet Maintenance Area	4E-06	4E-07	0.08	0.03
Offices and Parking Lot	3E-06	4E-07	0.03	0.01
Substation #7	2E-05	6E-07	0.3	0.02
Transformer Shop	2E-03	3E-05	124	8
Vehicle Refueling Area	1E-06	1E-07	0.03	0.01

Notes:
Blue highlighting indicates that cumulative cancer risk exceeds 10^{-6} but is less than or equal to 10^{-4}.
Yellow highlighting indicates that cumulative risk exceeds 10^{-4} or the target endpoint HI exceeds 1.
[a] Highest target endpoint HI.

COPCs with potential risks greater than 1×10^{-6} or a target endpoint HI above 1 under the RME scenario include:

COPC	Risk/ HI	Warehouse and Laydown Area	Salvage Yard and Storage Area	Stores and Fleet Maintenance Area	Substation #7	Transformer Shop
2,3,7,8-TCDD-TEQ	Risk	--	4E-06	--	--	--
	HI	--	--	--	--	--
Arsenic	Risk	1E-05	4E-06	2E-06	1E-05	--
	HI	--	--	--	--	--
Total PCBs	Risk	5E-06	2E-06	--	4E-06	2E-03
	HI	--	--	--	--	124

Notes:
-- Indicates that cancer risk is less than or equal to 10^{-6} or HI is less than or equal to 1.
Blue highlighting indicates that risk exceeds 10^{-6} but is less than or equal to 10^{-4}.
Yellow highlighting indicates that risk exceeds 10^{-4} or the target endpoint HI exceeds 1.

While the total potential cancer risk in the offices and parking lot area exceeds 10^{-6}, there are no individual COPCs with cancer risks greater than 10^{-6}.

Under the CTE scenario, the only COPC with a potential cancer risk greater than 10^{-6} or an HI greater than 1 is total PCBs in the transformer shop, driven by direct-contact with soil. The target endpoint evaluation presented in **Attachment H** indicates that no other COPCs drive the exceedance of an HI of 1 on a target endpoint basis under the RME or CTE scenario.

The RME EPC of 2,013 mg/kg for total PCBs in the transformer shop area is based on 48 surface soil samples with total PCB concentrations ranging from less than 1 mg/kg to 8,800 mg/kg,[24] an average of 189 mg/kg, and a median value of 0.09 mg/kg. The next highest surface soil concentration of total PCBs (130 mg/kg) occurred at location SUSDP21-3M. Removal of the elevated total PCB value from the EPC derivation results in an RME EPC of 25 mg/kg, a cancer risk of $2x10^{-5}$, and an HI of 1.5. Because the estimated cancer risk and noncancer hazard in this area driven by elevated concentrations detected at a single sampling location out of 48 total samples, the results are associated with a high degree of uncertainty.

The RME surface soil EPC of 5.1 mg/kg for total PCBs in the substation #7 area is based on 13 surface soil samples. This EPC is the maximum detected concentration from location SUSDP20 in 2013. The next highest concentration of 0.42 mg/kg from location SUS201F results in an estimated cancer risk of $1x10^{-7}$,

[24] This concentration was detected in surface soil sample SUSDP21-3G, which had an elevated concentration of Aroclor-1248 (2,500 mg/kg initial analysis and 8,800 mg/kg in re-analysis). The higher concentration was used in the EPC derivation.

an order of magnitude below $1x10^{-6}$. Therefore, the estimated cancer risk, which is driven by one elevated concentration, is associated with a high degree of uncertainty.

While potential risks associated with arsenic exceed 10^{-6}, arsenic concentrations in soil are consistent with background in several areas of the Site, as further discussed in Section 6.5.

6.3.1.3 Future Indoor Industrial Worker

A future indoor industrial worker was evaluated for potential exposures to VOCs resulting from groundwater vapor intrusion into indoor air of a potential future building, as shown in **Attachment B**. Based on the screening level evaluation and maximum detected groundwater concentrations, potential cancer risks are within or below the USEPA target risk range of 10^{-4} to 10^{-6}. The total HI is greater than 1 along the southern boundary. Total potential risks and HI values are indicated in the table below. COPCs with potential risks greater than $1x10^{-6}$ or a target endpoint HI above 1 are indicated with highlighting in the tables below:

COPC	Potential Cancer Risk			
	Southern Boundary[a]	Northern Boundary (DP-60)	Downgradient Perimeter (TA19C1, TA19C2)	MW05A
Chloroform	4E-07	4E-06	ND	2E-07
Tetrachloroethylene	7E-06	7E-09	5E-07	2E-07
Trichloroethylene	6E-06	ND	8E-07	3E-07
Vinyl Chloride	2E-06	ND	ND	ND
Total	**2E-05**	**4E-06**	**1E-06**	**8E-07**

Notes:
ND – Not detected.
Blue highlighting indicates that the cumulative potential risk is within USEPA's target risk range of 10^{-6} to 10^{-4}.
(a) Wells with exceedances: DPA3, DPA4, DPA5, DPB10, DPB3, DPB5, DPB6, DPB7, DPB9, DPC4, DPC5, DPC7, MW09A, SUSDP09.

COPC	Potential Noncancer Hazard Index (HI)			
	Southern Boundary[a]	Northern Boundary (DP-60)	Downgradient Perimeter (TA19C1, TA19C2)	MW05A
Chloroform	0.0005	0.005	ND	0.0003
Tetrachloroethylene	2	0.002	0.1	0.06
Trichloroethylene	2	ND	0.3	0.1
Vinyl Chloride	0.01	ND	ND	ND
Total	**4**	**0.007**	**0.4**	**0.2**

Notes:
ND – Not detected.
Yellow highlighting indicates that the target endpoint HI exceeds one.
(a) Wells with exceedances: DPA3, DPA4, DPA5, DPB10, DPB3, DPB5, DPB6, DPB7, DPB9, DPC4, DPC5, DPC7, MW09A, SUSDP09.

6.3.1.4 Future Recreational Visitor

The recreational visitor receptor is assumed to be exposed to COPCs in surface soil via incidental ingestion and dermal contact, and via inhalation from particulates derived from surface soil. The recreational visitor is assumed to be potentially exposed to COPCs only in the hypothetical future park land/green space area. The risk characterization results for the recreational visitor receptor are presented in **Tables 6-9** through **6-12** as follows:

- Table 6-9 Total Potential Carcinogenic Risks for Recreational Visitor Receptor, RME
- Table 6-10 Total Potential Hazard Index for Recreational Visitor Receptor, RME
- Table 6-11 Total Potential Carcinogenic Risks for Recreational Visitor Receptor, CTE
- Table 6-12 Total Potential Hazard Index for Recreational Visitor Receptor, CTE

As shown in **Tables 6-9** and **6-11**, the total potential carcinogenic risks are below 10^{-6} for both the RME and CTE scenarios. As shown in **Tables 6-10** and **6-12**, the total potential noncarcinogenic hazards are below 1. The cumulative RME and CTE cancer risks and noncancer hazards for the recreational visitor are summarized in the following table.

Cumulative Risks/Hazards for Future Recreational Visitor Receptor Hypothetical Future Park Land/Green Space		
	Older Child/Teen	
Receptor	**Cancer**	**Noncancer [a]**
Recreational Visitor (RME)	7E-08	0.04
Recreational Visitor (CTE)	7E-09	0.009
Notes: [a] Highest target endpoint HI.		

6.3.2 Waterside Receptors

Risk characterization results for Waterside receptors are presented below.

6.3.2.1 Angler Receptor

The angler receptor is assumed to be exposed to COPCs in fringe surface sediment and surface water via incidental ingestion and dermal contact and to COPCs from ingestion of fish caught from the Upper Anacostia River. As described in Section 5.5.1, the evaluation of fish consumption risks considered a mixed fish diet; a catfish only diet is considered in the uncertainty analysis.

The risk characterization results for the angler receptor are presented in **Tables 6-13** through **6-16** for the Upper Anacostia River. To provide additional context, risk characterization results are also presented in **Tables 6-17** through **6-20** for the following four additional regional river reaches: the Lower Anacostia, the Upper Potomac, the Lower Potomac, and the Upstream Non-Tidal Anacostia River (background)**.** The results are presented in the following tables:

- Table 6-13 Total Potential Carcinogenic Risks for Angler Receptor, RME
- Table 6-14 Total Potential Hazard Index for Angler Receptor, RME
- Table 6-15 Total Potential Carcinogenic Risks for Angler Receptor, CTE
- Table 6-16 Total Potential Hazard Index for Angler Receptor, CTE
- Table 6-17 Total Potential Carcinogenic Risks for Angler Receptor, RME, Regional
- Table 6-18 Total Potential Hazard Index for Angler Receptor, RME, Regional
- Table 6-19 Total Potential Carcinogenic Risks for Angler Receptor, CTE, Regional
- Table 6-20 Total Potential Hazard Index for Angler Receptor, CTE, Regional

Note that exposure to fringe surface sediment and surface water were not evaluated for the regional reaches, as these areas are outside the boundary of the Waterside Investigation Area. Further, as indicated in Tables **6-13** to **6-16,** these pathways are minor contributors to total risk for the angler receptor.

As shown in these tables, the total potential carcinogenic risks (RME and CTE) are within the USEPA target risk range of 10^{-4} to 10^{-6} for all of the recreational angler scenarios except for the RME scenario for the Upper Potomac River reach. The total potential HI for the RME recreational angler exceeds the target noncancer HI of 1 for all reaches except for the Upstream Non-Tidal Anacostia River, as discussed further below. The exceedance of the noncancer target HI of 1 is due to PCBs in fish tissue (based on both total PCBs for eye, nail, and immune effects and PCB-TEQ for reproductive and developmental effects). The potential carcinogenic risks and noncarcinogenic hazards posed by direct contact with fringe surface sediment and surface water are within or below USEPA's target risk levels.

For the young child age group, which has the highest noncancer hazards, the highest RME target endpoint HI for the Upper Anacostia is 4 and is driven by total PCBs. RME target endpoint HIs for regional reaches range from 0.6 (Upstream Non-Tidal Anacostia River) to 10 (Upper Potomac, driven by total PCBs). The highest RME target endpoint HI for the downstream, Lower Anacostia River reach is 5 and is driven by PCBs. Using CTE assumptions, the noncancer HIs for all age groups and areas are at or below 1. The target endpoint evaluation provided in **Attachment H** indicates that no other COPCs drive the exceedance of an HI of 1 on a target endpoint basis.

The cumulative RME and CTE cancer risks and noncancer hazards for the recreational angler receptor are summarized in the following tables. The cumulative risks/hazards are presented separately by area for total PCBs and PCB-TEQ.

Cumulative Risks/Hazards for Recreational Angler Receptor (RME)					
Receptor	Cancer		Noncancer [a]		
	Adult/ Young Child	Older Child/Teen	Adult	Young Child	Older Child/Teen
Anacostia River [b]					
Upper Anacostia (Total PCBs)	4E-05	2E-05	2	3	2
Upper Anacostia (PCB-TEQ)	2E-05	9E-06	0.4	0.7	0.4
Background River Reaches [c]					
Upstream Non-Tidal Anacostia (Total PCBs)	7E-06	3E-06	0.4	0.6	0.4
Upstream Non-Tidal Anacostia (PCB-TEQ)	8E-06	3E-06	0.4	0.6	0.4
Regional River Reaches [c]					
Lower Anacostia (Total PCBs)	7E-05	3E-05	3	5	3
Lower Anacostia (PCB-TEQ)	9E-05	4E-05	2	3	2

Cumulative Risks/Hazards for Recreational Angler Receptor (RME)					
Receptor	Cancer		Noncancer [a]		
	Adult/ Young Child	Older Child/Teen	Adult	Young Child	Older Child/Teen
Lower Potomac (Total PCBs)	6E-05	2E-05	1	2	1
Lower Potomac (PCB-TEQ)	6E-05	3E-05	0.7	1	0.7
Upper Potomac (Total PCBs)	2E-04	7E-05	9	10	9
Upper Potomac (PCB-TEQ)	2E-04	1E-04	6	9	5

Notes:
Blue highlighting indicates that cumulative risk exceeds 10^{-6} but is less than or equal to 10^{-4}.
Yellow highlighting indicates that cumulative risk exceeds 10^{-4} or the target endpoint HI exceeds 1.
[a] Highest target endpoint HI.
[b] Includes incidental ingestion and dermal contact with fringe surface sediment and surface water, and consumption of a mixed fish diet. Upper Anacostia encompasses the Waterside Investigation Area (**See Figure 3-7**).
[c] Includes consumption of a mixed fish diet.

Cumulative Risks/Hazards for Recreational Angler Receptor (CTE)					
Receptor	Cancer		Noncancer [a]		
	Adult/Young Child	Older Child/Teen	Adult	Young Child	Older Child/Teen
Anacostia River [b]					
Upper Anacostia (Total PCBs)	2E-06	1E-06	0.2	0.3	0.2
Upper Anacostia (PCB-TEQ)	1E-06	5E-07	0.03	0.06	0.04
Background Area [c]					
Upstream Non-Tidal Anacostia (Total PCBs)	5E-07	2E-07	0.08	0.1	0.03
Upstream Non-Tidal Anacostia (PCB-TEQ)	5E-07	3E-07	0.08	0.1	0.03
Regional Reaches [c]					
Lower Anacostia (Total PCBs)	3E-06	2E-06	0.3	0.5	0.4
Lower Anacostia (PCB-TEQ)	4E-06	2E-06	0.2	0.3	0.2
Lower Potomac (Total PCBs)	2E-06	1E-06	0.2	0.3	0.2
Lower Potomac (PCB-TEQ)	2E-06	1E-06	0.08	0.1	0.08
Upper Potomac (Total PCBs)	5E-06	2E-06	0.5	0.7	0.5
Upper Potomac (PCB-TEQ)	7E-06	3E-06	0.3	0.5	0.4

Notes:
Blue highlighting indicates that cumulative risk exceeds 10^{-6} but is less than or equal to 10^{-4}.
[a] Highest target endpoint HI.
[b] Includes incidental ingestion and dermal contact with fringe surface sediment and surface water, and consumption of a mixed fish diet. Upper Anacostia encompasses the Waterside Investigation Area (see **Figure 3-7**).
[c] Includes consumption of a mixed fish diet.

COPCs with potential risks greater than 1×10^{-6} or an HI above 1 under the RME scenario based on the combined adult and child for cancer and the child for non-cancer include:

COPCs with Risks Greater than 10^{-6} and Hazards above 1 RME Scenario							
COPC	**Risk/ HI**	**Upper Anacostia[a]**	**Lower Anacostia[b]**	**Upper Potomac[b]**	**Lower Potomac[b]**	**Upstream Non-Tidal Anacostia[b]**
PCBs and Dioxins						
Total PCBs	Risk	3E-05	5E-05	1E-04	2E-05	3E-06
	HI	3	5	14	2	--
PCB-TEQ	Risk	1E-05	7E-05	2E-04	3E-05	4E-06
	HI	--	3	9	--	--
2,3,7,8-TCDD-TEQ	Risk	2E-06	--	--	--	--
Pesticides						
4,4-DDE	Risk	--	--	4E-06	--	--
Dieldrin	Risk	5E-06	1E-05	2E-05	5E-06	--
Heptachlor epoxide	Risk	--	2E-06	--	--	--
Inorganics						
Arsenic	Risk	--	2E-06	3E-06	3E-05	--

Notes:
-- Indicates that cancer risk is less than or equal to 10^{-6} or HI is less than or equal to 1. Risk is presented for the sum of the adult and the young child, and the HI is presented for the young child. The older child/teen risk and HI values are lower.
Blue highlighting indicates that risk exceeds 10^{-6} but is less than or equal to 10^{-4}.
Yellow highlighting indicates that cancer risk exceeds 10^{-4} or the target endpoint HI exceeds 1.
[a] Upper Anacostia encompasses the Waterside Investigation Area (see **Figure 3-7**). Potential cancer risks and noncancer hazards include fish consumption and direct contact with fringe surface sediment and surface water.
[b] Potential risks and hazards include fish consumption only.

Under the CTE scenario, total PCBs (in fish tissue) exceeds $1x10^{-6}$ in the Upper Anacostia (but is less than $1x10^{-5}$). Total PCBs and PCB-TEQ (in fish tissue) exceeds $1x10^{-6}$ in the Lower Anacostia and the Upper Potomac, as indicated below. All CTE HIs are below 1.

COPCs with Risks Greater than 10^{-6} and Hazards above 1 CTE Scenario						
COPC	**Risk**	**Upper Anacostia[a]**	**Lower Anacostia[b]**	**Upper Potomac[b]**	**Lower Potomac[b]**	**Upstream Non-Tidal Anacostia[b]**
PCBs and Dioxins						
Total PCBs	Risk	2E-06	3E-06	4E-06	--	--
PCB-TEQ	Risk	--	3E-06	6E-06	--	--

Notes:
-- Indicates that cancer risk is less than or equal to 10^{-6}. Risk is presented for the sum of the adult and the young child. The older child/teen risk is lower.
Blue highlighting indicates that risk exceeds 10^{-6} but is less than or equal to 10^{-4}.
[a] Upper Anacostia encompasses the Waterside Investigation Area (see **Figure 3-7**). Potential cancer risks and noncancer hazards include fish consumption and direct contact with fringe surface sediment and surface water. Potential risks and hazards are driven by fish consumption.
[b] Potential risks include fish consumption only.

6.3.2.2 Swimmer Receptor

The swimmer receptor is assumed to be exposed to COPCs in fringe surface sediment and surface water via incidental ingestion and dermal contact (all three age groups). The risk characterization results for the swimmer receptor are presented in **Tables 6-21** through **6-24** as follows:

- Table 6-21 Total Potential Carcinogenic Risks for Swimmer Receptor, RME
- Table 6-22 Total Potential Hazard Index for Swimmer Receptor, RME
- Table 6-23 Total Potential Carcinogenic Risks for Swimmer Receptor, CTE
- Table 6-24 Total Potential Hazard Index for Swimmer Receptor, CTE

As shown in **Tables 6-21** and **6-23**, the total potential carcinogenic risks are within or below the USEPA target risk range of 10^{-6} to 10^{-4} for the RME and CTE scenarios. As shown in **Tables 6-22** and **6-24**, the total potential noncarcinogenic hazards are below the USEPA target HI of 1 for the RME and CTE scenarios. The cumulative RME and CTE cancer risks and noncancer hazards for the swimmer receptor are summarized in the following table.

Cumulative Risks/Hazards for Swimmer Receptor					
Receptor	Cancer		Noncancer [a]		
	Adult/Young Child	Older Child/Teen	Adult	Young Child	Older Child/Teen
Swimmer (RME)	2E-06	7E-07	0.03	0.08	0.03
Swimmer (CTE)	9E-08	7E-08	0.001	0.008	0.003

Notes:
Blue highlighting indicates that cumulative risk exceeds 10^{-6} but is less than or equal to 10^{-4}.
[a] Highest target endpoint HI.

There are no COPCs with an individual risk greater than 10^{-6} or an HI greater than 1.

6.3.2.3 Wader Receptor

The wader receptor is assumed to be exposed to COPCs in fringe surface sediment and surface water via incidental ingestion and dermal contact (all three age groups). The risk characterization results for the wader receptor are presented in **Tables 6-25** through **6-28**, as follows:

- Table 6-25 Total Potential Carcinogenic Risks for Wader Receptor, RME
- Table 6-26 Total Potential Hazard Index for Wader Receptor, RME
- Table 6-27 Total Potential Carcinogenic Risks for Wader Receptor, CTE
- Table 6-28 Total Potential Hazard Index for Wader Receptor, CTE

As shown in **Tables 6-25** and **6-27**, the total potential carcinogenic risks are within or below the USEPA target risk range of 10^{-4} to 10^{-6} for the RME and CTE scenarios. As shown in **Tables 6-26** and **6-28**, the total potential noncarcinogenic hazards are below the USEPA target HI of 1 for the RME and CTE scenarios. The cumulative RME and CTE cancer risks and noncancer hazards for the wader receptor are summarized in the following table.

Cumulative Risks/Hazards for Wader Receptor					
Receptor	Cancer		Noncancer [a]		
	Adult/Young Child	Older Child/Teen	Adult	Young Child	Older Child/Teen
Wader (RME)	4E-06	1E-06	0.04	0.2	0.05
Wader (CTE)	2E-07	1E-07	0.004	0.02	0.006

Notes:
Blue highlighting indicates that cumulative risk exceeds 10^{-6} but is less than or equal to 10^{-4}.
[a] Highest target endpoint HI.

The only COPC with a potential risk greater than 10^{-6} is 2,3,7,8-TCDD-TEQ for the adult/child receptor RME scenario. The potential risk is driven by direct contact with fringe surface sediment. There are no COPCs with an HI greater than 1.

6.3.2.4 Shoreline Worker Receptor

The shoreline worker receptor is assumed to be exposed to COPCs in fringe surface sediment and surface water via incidental ingestion and dermal contact (adult age group). The risk characterization results for the wader receptor are presented in **Tables 6-17** through **6-20**, as follows:

- Table 6-29 Total Potential Carcinogenic Risks for Shoreline Worker Receptor, RME
- Table 6-30 Total Potential Hazard Index for Shoreline Worker Receptor, RME
- Table 6-31 Total Potential Carcinogenic Risks for Shoreline Worker Receptor, CTE
- Table 6-32 Total Potential Hazard Index for Shoreline Worker Receptor, CTE

As shown in **Tables 6-29** and **6-31**, the total potential carcinogenic risks are within or below the USEPA target risk range of 10^{-4} to 10^{-6} for the RME and CTE scenarios. As shown in **Tables 6-30** and **6-32**, the total potential noncarcinogenic hazards are below the USEPA target HI of 1 for the RME and CTE scenarios. The cumulative RME and CTE cancer risks and noncancer hazards for the shoreline worker receptor are summarized in the following table.

Cumulative Risks/Hazards for Shoreline Worker Receptor		
	Cancer	Noncancer [a]
Receptor	Adult	Adult
Shoreline Worker (RME)	4E-06	0.09
Shoreline Worker (CTE)	1E-07	0.008

Notes:
Blue highlighting indicates that cumulative risk exceeds 10^{-6} but is less than or equal to 10^{-4}.
[a] Highest target endpoint HI.

The only COPC with a potential risk greater than 10^{-6} is 2,3,7,8-TCDD-TEQ under the RME scenario. The potential risk is driven by direct contact with fringe surface sediment. There are no COPCs with an HI greater than 1.

6.4 Potential COCs

Per DOEE's request, potential COCs are identified in this BHHRA as those COPCs with individual cancer risks greater than 1 x 10^{-6} or a target endpoint HI greater than 1.

6.4.1 Landside Investigation Area

The table below presents the potential COCs with potential risks greater than 10^{-6} or a target endpoint HI of 1 for the Landside Investigation Area; the hazard value representing the highest target endpoint HI is presented.

Potential COC	Risk/HI	Landside Investigation Area				
		Warehouse and Laydown Area	Salvage Yard and Storage Area	Stores and Fleet Maintenance Area	Substation #7	Transformer Shop
2,3,7,8-TCDD-TEQ	Risk	--	4E-06[a]	--	--	--
Arsenic	Risk	1E-05	4E-06[a]	2E-06[a]	1E-05[a]	--
Vanadium	HI	3[b]	--	--	--	--
Total PCBs	Risk	5E-06[a]	2E-06[a]	--	4E-6[a]	2E-03[a]
	HI	--	--	--	--	124[a] 1.6[b]

Notes:
-- Indicates that cancer risk is less than or equal to 10^{-6} or HI is less than or equal to 1.
Blue highlighting indicates that risk exceeds 10^{-6} but is less than or equal to 10^{-4}.
Yellow highlighting indicates that risk exceeds 10^{-4} or the target endpoint HI exceeds 1.
[a] Future outdoor industrial worker surface soil (0-1 foot bgs).
[b] Current/future construction worker soil (0-16 feet bgs).

As shown in the table above, arsenic in on-Site soil was found to pose a potential risk in excess of 10^{-6}, however, the background evaluation (see Section 6.5) found that arsenic concentrations in on-Site soil are consistent with background. Therefore, arsenic is not identified as a potential Landside soil COC.

Based on the conservative screening level evaluation of the vapor intrusion pathway, the following table presents the COCs identified for the potential future scenario in which a building is constructed along the southern or northern property boundary. The hazard value representing the highest target endpoint HI is presented.

COPC	Risk/HI	Potential COCs for the Future Vapor Intrusion Pathway[a]	
		Southern Boundary (a)	Northern Boundary (DP-60)
Chloroform	Risk	--	4E-06
Tetrachloroethylene	Risk	7E-06	--
	HI	2	--
Trichloroethylene	Risk	6E-06	--
	HI	2	--
Vinyl Chloride	Risk	2E-06	--

Notes:
-- Indicates that cancer risk is less than or equal to 10^{-6} or HI is less than or equal to 1.
Blue highlighting indicates that risk exceeds 10^{-6} but is less than or equal to 10^{-4}.
Yellow highlighting indicates that risk exceeds 10^{-4} or the target endpoint HI exceeds 1.
[a] Future outdoor industrial worker.

6.4.2 Waterside Investigation Area

The table below presents the potential COCs with potential risks greater than 10^{-6} or a target endpoint HI of 1 for the Upper Anacostia River and the Waterside Investigation Area; the hazard value representing the highest target endpoint HI is presented.

Potential COC	Risk/HI	Fish Tissue [a]	Fringe Surface Sediment
		Upper Anacostia	Pepco Waterside Investigation Area
2,3,7,8-TCDD-TEQ	Risk	--	2E-06 [a] 3E-06 [b,c]
Total PCBs	Risk	3E-05	--
	HI	3	--
PCB-TEQ	Risk	1E-05	--
Dieldrin	Risk	5E-06	--

Notes:
-- Indicates that cancer risk is less than or equal to 10^{-6} or HI is less than or equal to 1. Risk is presented for the sum of the adult and the young child, and the HI is presented for the young child. The older child/teen risk and HI values are lower.
Blue highlighting indicates that risk exceeds 10^{-6} but is less than or equal to 10^{-4}.
Yellow highlighting indicates that risk exceeds 10^{-4} or the target endpoint HI exceeds 1.
[a] Current/future recreational angler.
[b] Current/future shoreline worker.
[c] Current/future wader.

The potential COCs for all receptors and exposure scenarios are summarized in the following table.

Potential COC	Landside		Waterside	
	Soil	Groundwater (Vapor Intrusion)	Fringe Surface Sediment	Upper Anacostia Fish Tissue
2,3,7,8-TCDD-TEQ	X [a]		X	
Arsenic	X [b]			
Vanadium	X [c]			
Total PCBs	X [d]			X
PCB-TEQ				X
Dieldrin				X
Chloroform		X [e]		
Tetrachloroethylene		X [f]		
Trichloroethylene		X [f]		
Vinyl Chloride		X [f]		

Notes:
Blue highlighting indicates that risk exceeds 10^{-6} but is less than or equal to 10^{-4}.
Yellow highlighting indicates that risk exceeds 10^{-4} or the target endpoint HI exceeds 1.
Highlighting indicates that cumulative risks exceed 10^{-4} or the target endpoint HIs exceed one.
[a] Salvage yard and storage area, surface soil.
[b] Warehouse and laydown area, salvage yard and storage area, stores and fleet maintenance area, substation #7. Surface soil.
[c] Warehouse and laydown area, soil (0-16 feet bgs).
[d] Warehouse and laydown area, surface soil. Transformer shop, soil (0-16 feet bgs).
[e] Northern boundary.
[f] Southern boundary.

6.5 Evaluation of Background and Regional Fish Tissue Data

6.5.1 Background Evaluation

Accounting for background area information is integral to evaluating risks posed by the release of hazardous substances in the Study Area. USEPA (2002e) notes that a primary objective of CERCLA risk assessments is to provide information on risks that can be effectively addressed through remedial actions. USEPA (2002e) states, “Specifically, the COPCs with high background concentrations should be discussed in the risk characterization, and if data are available, the contribution of background to site concentrations should be distinguished.” Taking background area information into account during the risk assessment process informs the understanding of risks associated with site releases, as opposed to risks resulting from the presence of constituents that may have migrated into the site, or that may reflect regional conditions related to human activities (Judd et al. 2003).

USEPA (2002d) defines background as: “Substances or locations that are not influenced by the releases from a site and are usually described as naturally occurring or anthropogenic: (1) Naturally occurring substances are present in the environment in forms that have not been influenced by human activity; (2) Anthropogenic substances are natural and human-made substances present in the environment as a result of human activities (not specifically related to the CERCLA site in question).” It further defines a background reference area as: “The area where background samples are collected for comparison with samples collected on site. The reference area should have the same physical, chemical, geological, and biological characteristics as the site being investigated, but has not been affected by activities on the site.” Based on these definitions, the most appropriate data sets from which to obtain information on background and reference information are those collected from areas that have similar characteristics to the environment of the Site and the Anacostia River.

Appendix W of the RI Report describes the methodology of the refined background evaluation for each environmental medium. The refined background evaluation methodology includes both graphical and statistical evaluations. Graphical evaluation includes boxplots, probability plots, and index plots. Statistical analyses include distribution testing, outlier testing, calculation of background threshold value (BTV) statistics, and population tests. Outliers were removed prior to calculating BTVs and running population tests, as described in Appendix W of the RI Report. The 95% upper tolerance limit was selected as the BTV statistic. A two-sample hypothesis test was conducted for each COPC for which sufficient data were available. The tests selected for each COPC was determined by the distributions of the Study Area and background data sets. Appendix W provides results for the COPCs included in the background evaluation; this section summarizes the results for potential COCs in Landside Investigation Area soil and Anacostia River fringe surface sediment.

Soil

2,3,7,8-TCDD-TEQ, total PCBs, and arsenic were identified as potential COCs in surface soil, and total PCBs and vanadium were identified as potential COCs in combined surface and subsurface soil (0 to 16 feet bgs).

The maximum detected concentrations of arsenic in the salvage yard and waste storage area and the stores and fleet maintenance yard are below the BTV of 17 mg/kg, indicating that levels of arsenic in these areas are likely to be consistent with background. Arsenic concentrations in the warehouse and laydown area exceed the BTV. However, the results of the two-sample hypothesis test indicate that Site arsenic concentrations are not greater than background concentrations, which is further supported by the boxplot comparisons provided in Appendix W of the RI Report. Therefore, the background evaluation supports the conclusion that arsenic concentrations on Site are background related and that arsenic is not a Site COC.

Concentrations of 2,3,7,8-TCDD-TEQ, total PCBs, and vanadium exceed BTVs, and the results of the hypothesis tests indicate that Site concentrations of 2,3,7,8-TCDD-TEQ and vanadium are greater than or equal to background. Hypothesis testing could not be conducted on total PCBs due to low frequency of detection in background.

Anacostia River

Sediment and fish tissue in the Anacostia River have been affected by ongoing and historic sources of contamination, as well as stormwater discharges, sewage overflows, and other permitted discharges. These sources contribute to the cumulative exposure of human and ecological receptors in the Anacostia River. The surface sediment background evaluation is discussed below.

As discussed in Section 3.1.4.1, Pepco performed an analysis of potential tidal influence to confirm that all sediment sampling locations included in the Site-specific background dataset were upstream of any potential influence from the Site. The details of the analysis and the results are provided in Appendix W. Pepco's analysis confirms that the background location SEDBACK 20 and background locations upstream of SEDBACK 20 will not be influenced by any Site-related contaminants as a result of tidal exchanges. No sampling locations downstream of SEDBACK 20 were included in the dataset for the purpose of calculating site-specific background values.

BTVs were derived for surface sediment in Appendix W of the RI Report. 2,3,7,8-TCDD-TEQ was identified as a potential COC in this BHHRA based on a potential risk of $3x10^{-6}$ for the wader adult/child and of $2x10^{-6}$ for the shoreline worker potentially exposed to fringe surface sediment. Both the maximum detected concentration (0.0007 mg/kg) and the 95% UCL (0.0002 mg/kg) exceed the BTV of 0.00001 mg/kg). The results of the hypothesis tests indicate that Waterside Investigation Area concentrations of 2,3,7,8-TCDD-TEQ in surface sediment are greater than or equal to background.

6.5.2 Regional Area Fish Tissue Evaluation

The available tissue data are insufficient for calculation of background statistics. Therefore, BTVs were not derived for fish tissue. Appendix W of the RI Report provides a graphical comparison of fish tissue concentrations between the Upper Anacostia reach and regional reaches:

- Upper Anacostia River Area (upstream of the CSX bridge); includes the Waterside Investigation Area, and extends approximately 1.3 miles downstream and 1.9 miles upstream of Benning Road

- Lower Anacostia River Area (downstream of the CSX bridge);
- Lower Potomac River (downstream of the 14th Street bridge);
- Upper Potomac River (upstream of the 14th Street bridge);
- Upstream Non-Tidal Anacostia River (north of the Maryland state line); upstream of the Waterside Investigation Area; background area

In addition to the graphical comparison of fish tissue concentrations, potential fish consumption risks and hazards were calculated for a background river reach (Upstream Non-Tidal Anacostia) and three nearby regional river reaches (Lower Anacostia, Lower Potomac, Upper Potomac) to provide important context for the Upper Anacostia fish consumption risks and hazards. Potential risks exceed 10^{-4} for fish consumption in the Upper Potomac reach primarily due to PCBs, and in the Lower Potomac reach primarily due to PCBs and arsenic. The HI exceeds 1 in the Potomac River reaches and in the Lower Anacostia reach due to PCBs. For comparative purposes, the table below presents the chemicals with potential risks greater than 10^{-6} or a target endpoint HI of 1 for each of these river reaches; the hazard value representing the highest target endpoint HI is presented. As shown, all of the chemicals identified as potential COCs in the Upper Anacostia reach for fish consumption are also identified in other river reaches in the region, and in many cases, at higher risk and hazard levels. These results are indicative of a regional impact on fish tissue body burdens that may be attributable, at least in part, to sources other than sediment within the Upper Anacostia River reach or the Waterside Investigation Area in particular.

Chemical	Risk/ HI	Fish Tissue [a] RME Scenario			
		Regional Reaches			Background Area
		Lower Anacostia	Lower Potomac	Upper Potomac	Upstream Non-Tidal Anacostia
Arsenic	Risk	2E-06	3E-05	3E-06	--
Total PCBs	Risk	5E-05	2E-05	1E-04	3E-06
	HI	5	2	14	--
PCB-TEQ	Risk	7E-05	3E-05	2E-04	4E-06
	HI	3	--	9	--
4,4-DDE	Risk	--	--	4E-06	
Dieldrin	Risk	1E-05	5E-06	2E-05	
Heptachlor epoxide	Risk	2E-06	--	--	

Notes:
-- Indicates that risk is less than or equal to 10^{-6} or HI is less than or equal to 1. Risk is presented for the sum of the adult and the young child, and the HI is presented for the young child. The older child/teen risk and HI values are lower.
Blue highlighting indicates that cumulative risk exceeds 10^{-6} but is less than or equal to 10^{-4}.
Yellow Highlighting indicates that cumulative risk exceeds 10^{-4} or the target endpoint HI exceeds 1.
[a] Current/future recreational angler.

Potential risks and hazards were highest in the Upper Potomac River and lowest in the Upstream Non-Tidal Anacostia River. Potential risks and hazards for the Upper Anacostia fall within the range of potential risks and hazards in the regional reaches (i.e., Potomac River, Upstream Non-Tidal Anacostia, and Lower Anacostia), as indicated in the graphs below.

7 Uncertainty Analysis

Within any of the four steps of the human health risk assessment process, assumptions must be made due to a lack of absolute scientific knowledge. Some of the assumptions are supported by considerable scientific evidence, while others have less support. Every assumption introduces some degree of uncertainty into the risk assessment process. Regulatory risk assessment methodology requires that conservative assumptions be made throughout the risk assessment to ensure that risks are not underestimated. Therefore, when all of the conservative assumptions and approaches are combined, it is more likely that risk results are overestimated rather than underestimated.

The assumptions that introduce the greatest amount of uncertainty in this risk assessment are discussed in this section. The assumptions for which there is not enough information available to assign a numerical value to the uncertainty, and thus cannot be factored into the calculation of risk, are discussed in qualitative terms. In some cases, alternate assumptions are available that are as plausible as the assumptions used in the BHHRA. In some of these cases, the uncertainty is evaluated quantitatively. These uncertainties may also be incorporated into the risk management process during the development of remediation goals, as part of the Feasibility Study. Section 7.1 discusses uncertainty related to data evaluation and COPC selection. Section 7.2 discusses uncertainties related to the toxicity assessment. Section 7.3 discusses uncertainties related to the exposure assessment. Lastly, Section 7.4 discusses uncertainties related to the risk characterization.

7.1 Data Evaluation and COPC Selection

7.1.1 Adequacy and Quality of Analytical Data

The data collected as part of the Study Area RI between 2012 and 2017, as well as biological tissue data from the Anacostia River collected under other agency programs, serve as the basis for the BHHRA. Multiple media were sampled using a sound conceptual understanding of Study Area conditions. As new information was generated, the CSM was refined and used to guide subsequent data gathering efforts. Thus, while it was not possible to sample every location at the Study Area, the extensive soil, groundwater, sediment, and surface water data collected, combined with the knowledge of source areas and potential migration pathways, provide a high degree of confidence that the range of impacts and environmental conditions have been characterized. However, the fish fillet data set for the Upper Anacostia River (which includes the Waterside Investigation Area) is small (seven composite samples). These data may not be representative of the Waterside Investigation Area because of the uncertainty associated with fish home ranges, where the samples were collected within the reach, and bioaccumulation into fish. The uncertainty associated with the limited fish fillet data set is discussed below and in in Section 7.1.2.

Generally, in the site characterization phase of the site assessment, knowledge of past and current use of the study area is used to guide investigations and determine which parameters are analyzed and what analytical methods are employed for the detection of chemicals in the relevant environmental media at the site. While the suite of analytes for this BHHRA included multiple chemical groups, including metals, VOCs, SVOCs, PAHs, pesticides, PCBs, and dioxins and furans, it is possible that chemicals not sampled for may be present at the Study Area. Should this be the case, Study Area risks may be incomplete depending on the nature of the chemicals not included in the sample analyses. Given the high degree of historical knowledge of Site operations and the CSM, it is unlikely that significant concentrations of other chemicals are present. Therefore, it is likely that the primary chemicals of human health concern at the Study Area have been captured in the data set used for the BHHRA.

The fish tissue data set forming the basis of the BHHRA is small; only 7 fillet samples are available for the Upper Anacostia. Fewer than 10 samples are available in each of the Upper and Lower Potomac and Lower Anacostia areas. Furthermore, these data were collected in 2013 and may not be representative of current conditions, as concentrations have been generally declining over time (see graphic in Section 3.1.4.3).

As noted previously, the Pepco 2013 surface water data were used in the BHHRA and were not supplemented with DOEE data. The uncertainty associated with this is low, as surface water is a minor contributor to total risk (i.e., less than 10^{-6} and an HI of 1). The risk assessment for the ARSP also did not identify any potential risks associated with surface water in Reach 456 (the reach that encompasses the Waterside Investigation Area) greater than 10^{-6} or an HI of 1 (TetraTech, 2018).

As discussed in Section 3.1, laboratory results collected under the Pepco RI program were subjected to data validation conducted in accordance with the approved QAPP (AECOM, 2012) prior to use in the BHHRA. Where necessary, qualifiers were applied to the data due to quality control non-conformances. The vast majority of the data generated were found to be reliable and acceptable for use in risk assessment and remedial decision-making. Out of over 550,000 validated results, only about 500 (less than 0.1%) were rejected and deemed not usable for project decisions. These rejected result values were removed from the database used for the risk assessments. TetraTech conducted Phase 2B validation of the fish tissue data sets collected by DOEE (Pinkney, 2017, TetraTech, 2018). Pinkney (2017) noted that quality assurance procedures followed included the analysis of blanks, laboratory and field replicates, and standard reference materials. The DOEE fringe surface sediment sample results used in this BHHRA were also validated by TetraTech (2018).

The use of laboratory J-qualified data adds some uncertainty to the risk assessment by definition, as the true concentration lies between the method detection limit and the sample quantitation limit. However, the estimated value given for each J qualified result is considered the best estimate of the true concentration, and was therefore used in risk calculations (USEPA, 1989a).

Given that the vast majority of the Study Area data were determined to be valid and acceptable for use in the risk assessments, there is a high degree of confidence in the quality of the data used in the BHHRA for soil, groundwater, fringe surface sediment, and surface water. This reduced uncertainty translates to a high degree of confidence in the use of the project data in risk-based decision-making. There is a higher degree of uncertainty associated with the fish tissue data set due to the small size and other considerations as discussed below.

7.1.2 Representativeness of Fish Tissue Data

There is uncertainty associated with the tissue data used to estimate potential fish consumption risk. The fish tissue samples collected in 2013 in the Upper Anacostia River sampling area (from the CSX railroad bridge up to the Maryland state line) may not be representative of the Waterside Investigation Area. The Upper Anacostia River sampling area of approximately 3.2 miles extends approximately 1.3 miles downstream and 1.9 miles upstream of Benning Road (**Figure 3-7**), and these data were not collected to evaluate contaminant sources, but rather for monitoring fish tissue contaminant levels and changes over time (Pinkney, 2017). Fish specimens caught throughout this area were combined to create one composite sample per species to represent the Upper Anacostia River sampling area. Fish species vary in how far they will travel for food and spawning; for example, sunfish typically have a small home range (e.g., 0.23 to 1.12 hectares; Fish and Savitz [1983]), whereas brown bullhead have been found to have a home range of up to 1.3 miles in the Anacostia River (Sakaris et al., 2005). Based on the sample design as well as varying home ranges of the species sampled, the concentrations of contaminants detected in the fish tissue composite samples are expected to represent conditions throughout the approximately 3.2-mile Upper Anacostia River sampling area (see **Figure 3-7**), but they are not necessarily representative of conditions in the Waterside Investigation Area, an area of approximately one-half mile of shoreline.

7.1.3 Analysis for PCBs via Aroclor versus Congeners

The BHHRA was conducted using available PCB congener data for fish tissue. Per the approved RI work plan, PCB Aroclor analysis was performed, and the Aroclor data were used in the BHHRA for soil, groundwater, fringe surface sediment, and surface water. The Aroclor data set is more extensive than the congener data set for the Study Area. However, due to differences in the analytical methods, the use of Aroclor versus congener data represents a potential source of uncertainty in the BHHRA. A subset of soil, groundwater, and fringe surface sediment samples were analyzed for both Aroclors and congeners, allowing for comparison of the two sets of PCB concentrations, as discussed below.

7.1.3.1 Soil

A total of 31 Site soil samples (14 surface and 17 subsurface) were analyzed for both PCB Aroclors and congeners. The ratio of total PCB congeners to total PCB Aroclors ranged from less than 1 (i.e., total concentration was higher based on Aroclor data) to 59, with an average of 5 and a median of 1.5 (**Table 7-1**). These data suggest that the concentration of total PCBs based on the sum of congeners would generally be higher than the sum of Aroclors for soil samples at the Site.

Potential risks/hazards for total PCB Aroclors exceeded 10^{-6} or HI of 1 in surface soil in four areas for the future outdoor industrial worker (the warehouse and laydown area, substation #7, the salvage yard and waste storage area, and the transformer shop). If it were assumed that total PCB concentrations are on average 5 times higher than Aroclor concentrations in surface soil, the stores and fleet maintenance area would also be identified with total PCB risks greater than 10^{-6} (but less than 10^{-5}).

Potential risks and hazards for the hypothetical future recreational visitor associated with total PCBs in surface soil would remain well below 10^{-6} and an HI of 1 even, assuming a 5-fold increase in total PCB concentrations above detected levels of PCB Aroclors.

Potential risks and hazards for total PCB Aroclors exceeded 10^{-6} and an HI of 1 only in the transformer shop soil (0 to 16 feet bgs) for the construction worker. No additional exceedances would be identified based on a 5-fold increase in total PCB concentrations.

7.1.3.2 Groundwater

Monitoring wells were sampled and analyzed for PCB Aroclors in November 2014 and were mostly non-detect, with detections below the USEPA Maximum Contaminant Level (MCL) of 0.5 µg/L (USEPA, 2018g). Samples were collected and analyzed for PCB congeners in December 2014 and December 2016. PCB congeners were detected at relatively low concentrations, with total PCBs well below the MCL of 0.5 µg/L. Therefore, the uncertainty associated with the analytical method for PCBs in groundwater is low, particularly given that the only potential exposures to groundwater at the Site include inhalation of volatile COPCs and discharge to surface water, with considerable dilution between groundwater and surface water.

7.1.3.3 Fringe Surface Sediment

Sixteen fringe surface sediment samples from the Waterside Investigation Area were analyzed for both PCB Aroclors and PCB congeners (nine samples collected by TetraTech for the ARSP and seven samples collected by Pepco). The ratio of total PCB congeners to total PCB Aroclors ranged from less than 1 to 6.2, with an average of 2.3 and median of 2.1 (**Table 7-2**). Potential risks/hazards associated with total PCB Aroclors in fringe surface sediment did not exceed 10^{-6} or an HI of 1 for any receptor. Even assuming that total PCB congeners are present at as much as 6 times the total Aroclor concentration, potential risks and hazards would not exceed 10^{-6} or an HI of 1.

In summary, the use of PCB totals based on Aroclors results in some uncertainty in the risks and hazards presented in this BHHRA for abiotic media; however, the available data suggest that the risk assessment conclusions would not change substantially if congener data were used.

7.1.4 Adequacy of the COPC Selection Process

Not all chemicals detected in a study area are selected as COPCs for quantitative analysis for several reasons. Some chemicals may be present at levels below conservative screening levels. Others may be present at concentrations below sample detection limits. A USEPA review of the results of many risk assessments demonstrates that, in most cases, risks are attributable to a select few chemicals, and that many of the chemicals quantitatively evaluated do not contribute significantly to total risk estimates (USEPA, 1993a).

COPCs identified for evaluation in the BHHRA were described in Section 3. A total of 43 COPCs were identified for quantitative evaluation in the BHHRA, as presented in **Table 3-23**. As discussed in Section 3, the goal of the COPC selection is to include those chemicals that are the most toxic, prevalent, and environmentally persistent in the quantitative portion of the risk assessment. The screening process used to select COPCs for evaluation is intended to: (1) identify with a high degree of certainty those chemicals that can be safely eliminated from further evaluation because their contribution to total site risk is negligible; and (2) identify those chemicals that merit further evaluation (either quantitatively or qualitatively) based on their potential to adversely affect humans depending on specific types of exposures.

The approved COPC screening process for the BHHRA followed a logical approach based on comparison to RBSLs. The use of conservative screening levels, including risk-based concentrations deemed by USEPA to be acceptable for residential exposure to soil (as a surrogate for intermittent exposure to fringe surface sediment), ensures that the chemicals excluded from further evaluation would contribute negligibly to total risk. Therefore, not quantitatively evaluating the excluded chemicals will not measurably affect the numerical estimates of hazard or risk and, thus, will not affect remedial decision-making.

In the COPC selection process, it was assumed that only those chemicals detected are actually present. However, uncertainty can arise if the detection limits for chemicals that were not detected exceed the applicable screening levels. For example, PCBs were identified as a COPC for soil, fringe surface sediment, and fish tissue. PCBs were not detected in surface water using Method 8082, which has a nominal reporting limit of 0.010 µg/L. While this reporting limit is above the PCB national and DOEE water quality criterion for consumption of water and organisms (6.4E-05 µg/L), it is below the RSL for tap water consumption (0.044 µg/L). As previously discussed, use of the tap water RSLs to select COPCs for evaluating occasional surface water contact is highly conservative. However, as a conservative measure in this BHHRA, PCBs were identified as a surface water COPC and included in the risk calculations using the lowest reporting limit as a proxy EPC.

7.2 Dose-Response Assessment

The purpose of the dose-response assessment is to identify the types of adverse health effects a chemical may potentially cause and to define the relationship between the dose of a chemical and the likelihood or magnitude of an adverse effect (response). Risk assessment methodologies typically divide potential health effects of concern into two general categories: effects with a threshold (noncarcinogenic) and effects assumed to be without a threshold (potentially carcinogenic), although there is increasing scientific evidence that many carcinogens also act via a threshold mechanism. Toxicity assessments for both of these types of effects share many of the same sources of uncertainty. To compensate for these uncertainties, USEPA has developed toxicity values that are biased to overestimate rather than under-estimate human health risks. Several of the more important sources of uncertainty and the resulting biases are discussed below.

7.2.1 Animal-to-Human Extrapolation in Noncarcinogenic Dose-Response Evaluation

For many chemicals, animal studies provide the only reliable information on which to base an estimate of adverse human health effects. Oral RfDs are available for 33 COPCs, the majority of which are based on animal studies. RfDs for 2,3,7,8-TCDD-TEQ, inorganic arsenic, cobalt, manganese, and methyl mercury are based on human studies. Inhalation RfCs are available for 24 COPCs, of which 15 are based on animal studies. Extrapolation from animals to humans introduces a great deal of uncertainty into the risk characterization; where human studies are available, uncertainty is reduced. In most instances, it is not known how differently a human may react to the chemical compared to the animal species used to test the chemical. If a chemical's fate and the mechanisms by which it causes adverse effects are known in both animals and humans, uncertainty is reduced. When the fate and mechanism for the chemical are unknown, uncertainty increases.

The procedures used to extrapolate from animals to humans involve conservative assumptions and incorporate uncertainty factors such that overestimation of effects in humans is more likely than underestimation. When data are available from several species, the lowest dose that elicits effects in the most sensitive species is used for the calculation of the RfD. Uncertainty factors are applied to this dose, generally of 1 to 10 each, to account for intraspecies variability, interspecies variability, study duration, and/or extrapolation of a low effect level to a no effect level. Thus, most reference doses used in risk assessment are 100- to 10,000-fold lower than the lowest effect level found in laboratory animals. Uncertainty factors for chronic toxicity values included in this risk assessment range from 3 (arsenic and manganese RfDs) to 10,000 (DRO RfD), as shown in **Tables 4-1** and **4-3**.

Nevertheless, because the fate of a chemical can differ in animals and humans, it is possible that animal experiments will not reveal an adverse effect that would manifest itself in humans. This can result in an underestimation of the effects in humans. The opposite may also be true: effects observed in animals may not be observed in humans, resulting in an overestimation of potential adverse human health effects.

7.2.2 Evaluation of Carcinogenic Dose-Response

Significant uncertainties exist in estimating dose-response relationships for potential carcinogens. These are due to experimental and epidemiologic variability, as well as uncertainty in extrapolating both from animals to humans and from high to low doses. Three major issues affect the validity of toxicity assessments used to estimate potential excess lifetime cancer risks: (1) the selection of a study (i.e., data set, animal species, matrix in which the chemical is administered to the animal) upon which to base the calculations, (2) the conversion of the animal dose used to an equivalent human dose, and (3) the mathematical model used to extrapolate from experimental observations at high doses to the very low doses potentially encountered in the environment. CSFs are available for 29 of the COPCs, and inhalation unit risk factors are available for 38 COPCs.

7.2.2.1 Study Selection

Study selection involves the identification of a data set (experimental species and specific study) that provides sufficient, well-documented dose-response information to enable the derivation of a valid CSF. Human data (e.g., from epidemiological studies) are preferable to animal data, although adequate human data sets are relatively rare. Therefore, it is often necessary to develop dose-response information from a laboratory species, ideally one that biologically resembles humans (e.g., with respect to metabolism, physiology, and pharmacokinetics), and where the route of administration is similar to the expected mode of human exposure (e.g., inhalation and ingestion). It is also important to note that when multiple valid studies are available, the USEPA generally bases CSFs on the one study and site that show the most significant increase in tumor incidence with increasing dose. In some cases, this selection is made in spite of significant decreases of tumor incidence in other organs and total tumor incidence with increasing dose. Consequently, the current study selection criteria are likely to lead to overestimation of potential cancer risks in humans.

For example, the oral cancer slope factors for PCBs are based on rat studies, and USEPA (2018d) has classified PCBs as a “B2” carcinogen. Under the 1986 cancer classification scheme (USEPA, 1986), B2 carcinogens are defined as probably carcinogenic to humans based on evidence in animals, but with little or no human data. While PCBs have been demonstrated to produce tumors in animals, several studies have interpreted human epidemiological data as negative for carcinogenicity (Shields, 2006, Golden et al., 2003, Golden and Kimbrough, 2009). USEPA (2018d) has classified human data on the carcinogenicity of PCBs as inadequate.

7.2.2.2 Interspecies Dose Conversion

Only the CSF for inorganic arsenic and the URFs for arsenic and trichloroethylene are based on human studies. For CSFs/URFs based on animal studies, the USEPA derivation of human equivalent doses by conversion of doses administered to experimental animals requires the assumption that humans and animals are equally sensitive to the toxic effects of a substance, if the same dose per unit body surface area is absorbed by each species, and the mechanism of toxicity is the same. Although such an assumption may hold for direct-acting genotoxicants, it is not necessarily applicable to many indirect-acting carcinogens and likely overestimates potential risk by a factor of 6 to 12, depending on the study species (USEPA, 1992c). Further assumptions for dose conversions involve standardized scaling factors to account for differences between humans and experimental animals with respect to life span, body size, breathing rates, and other physiological parameters. In addition, evaluation of risks associated with one route of administration (e.g., inhalation) when tests in animals involve a different route (e.g., ingestion) requires additional assumptions with corresponding additional uncertainties.

7.2.2.3 High-to-Low Dose Extrapolation

The concentration of chemicals to which humans are potentially exposed in the environment is usually much lower than the levels used in the studies from which dose-response relationships are developed. Estimating potential health effects, therefore, requires the use of models that allow extrapolation of health effects from high experimental doses in animals to low environmental doses. These models are generally statistical in character and have an uncertain biological basis. Thus, the use of a model for dose extrapolation introduces uncertainty in the dose-response estimate. In addition, these models contain assumptions that may also introduce a large amount of uncertainty. Generally, the models have been developed to err on the side of overestimating rather than underestimating potential health risks.

Many of the USEPA CSFs/URFs listed in IRIS are derived using the upper 95% confidence limit of the slope predicted by the LMS model used to extrapolate low dose risk from high dose experimental data. USEPA recognizes that this method produces very conservative risk estimates, and that other mathematical models may exist. USEPA states that the upper-bound estimate generated by the LMS model leads to a plausible upper limit to the risk that is consistent with some of the proposed mechanisms of carcinogenesis. The true risk, however, is unknown and may be as low as zero.

The LMS model is very conservative, as it assumes strict linearity between the lowest dose that produced an effect and zero dose. According to USEPA (1989a), "Because the slope factor is often an upper 95th percentile confidence limit of the probability of response based on experimental animal data used in the multistage model, the carcinogenic risk estimate will generally be an upper-bound estimate. This means that USEPA is reasonably confident that the 'true risk' will not exceed the risk estimate derived through use of this model and is likely to be less than that predicted."

Moreover, the body has mechanisms to detoxify chemicals, especially at low doses, and mechanisms to repair damage if it should occur. Therefore, many scientists believe a number of chemicals cause cancer only above a "threshold" dose (as reviewed in Bradley, 1996). Consequently, the assumption that there is some probability of harm to human health at any level of exposure is very conservative and is expected to result in overestimates of risk, especially when coupled with the use of an upper-bound estimate of cancer potency.

USEPA's current carcinogen risk assessment guidelines (USEPA, 2005b) emphasize mode of action data, and recognize that some carcinogens may act in a nonlinear fashion. Therefore, it is recognized that some carcinogens may have a threshold dose below which effects would not be seen. For example, a threshold for carcinogenic activity has been demonstrated for chloroform and was used as the basis for USEPA's development of dose-response values for chloroform (USEPA, 2018b).

7.2.3 Potential Contribution from Early-Life Exposures to Lifetime Risk

Benzo(a)pyrene (and the six other potentially carcinogenic PAH COPCs), are assumed to act via a mutagenic mode of action. Potential cancer risks for these COPCs were adjusted upward using ADAFs to ensure that the potential contributions from early life exposures are not underestimated. Additionally, trichloroethylene and vinyl chloride are considered to be mutagenic, but are COPCs only for worker (adult) exposure pathways. Therefore, adjustments were not necessary because there are no assumed childhood exposures. For vinyl chloride, the cancer toxicity values based on exposure during adulthood were used.

PCBs are not assumed to exert carcinogenic effects via mutagenic activity. For pre-conception and in-utero life stages, exposure to bioaccumulative COPCs, such as PCBs, would be primarily through the mother's diet, as would exposure of nursing infants. If women of childbearing age, pregnant, or breastfeeding mothers consume large amounts of Anacostia River fish, they could potentially expose the unborn child or nursing infant to lipophilic COPCs and/or bioaccumulative COPCs (e.g., PCBs).

7.2.4 Dioxin-Like Toxicity

Certain PCB congeners have been identified as having a mechanism of toxicity similar to that of 2,3,7,8-TCDD (Van den Berg et al., 2006; USEPA, 2010). The designation as a "dioxin-like compound" is based on Ah receptor binding and similarities in biochemical activity and bioaccumulation potential. Twelve coplanar PCBs with four or more chlorines with one or no substitutions at ortho positions have been identified as having dioxin-like toxicity, and TEFs have been developed to equate the toxicity of each dioxin-like PCB congener to that of 2,3,7,8-TCDD (USEPA, 2010). The "coplanar" PCBs lack ortho chlorines on both rings, allowing the rings to orient in the same plane, but this conformation is not rigid. USEPA's December 2010 guidance adopts the 2005 WHO mammalian TEFs for the 12 coplanar PCBs, but also notes that when exposures are to a single chemical or class of chemicals such as PCBs, the use of the PCB cancer slope factors is sufficient (USEPA, 2010).

However, there is the potential for dioxin-like PCB congeners to preferentially bioaccumulate due to their resistance to metabolism and biodegradation. Therefore, USEPA guidance (1996, 2010) identifies a supplemental approach for evaluating the potential risks posed by PCBs that focuses on the 12 coplanar PCBs that are structurally similar to 2,3,7,8-TCDD and have the capacity to bind to the Ah receptor. The evaluation of the 12 dioxin-like PCBs (referred to as PCB-TEQ) is most applicable to estimating exposure via dietary uptake, because the TEFs are primarily based on oral uptake studies, often through the diet (Van den Berg et al., 2006). There is greater uncertainty in applying TEFs to other exposure pathways and abiotic media due to differences in bioavailability and fate. For the evaluation of the fish ingestion pathway, the potential cancer risks and noncancer hazards posed by PCBs were evaluated as PCB-TEQ, as well as total PCBs. This approach recognizes two potential mechanisms of toxicity and the potential for enrichment of certain presumed dioxin-like congeners in fish tissue.

7.2.4.1 Uncertainty in Application of TEFs to PCBs

The TEFs for dioxin-like PCBs were developed based on a database of laboratory studies in which the relative potency of a test chemical was compared to a reference chemical, usually 2,3,7,8-TCDD. There is uncertainty in the assumption that a subset of PCB congeners exerts toxicity in a manner similar to that of 2,3,7,8-TCDD. Dioxins and furans are rigidly planar molecules with centrally located oxygen atom(s), while PCBs are never truly coplanar and lack the central oxygen atoms. In addition, PCBs that are approximate stereoisomers of dioxin/furan Ah receptor agonists bind the receptor much more weakly than strong Ah receptor agonists such as dioxins and furans. Even with the most favorable chlorination pattern, the affinity of PCBs for the Ah receptor is not nearly that of potent dioxin/furans. Only a handful of Ah receptor agonists have been tested for human Ah receptor affinity even though marked species differences have been demonstrated. For example, 2,3,7,8-TCDD’s and other potent agonist’s affinity for the human Ah receptor is 10-fold less than the receptor affinity in ultra-sensitive animal models (Ema et al., 1994; Fan et al., 2009; Flaveny and Perdew, 2009; Zeiger et al., 2001; Westerink et al., 2008).

The National Research Council of the National Academy of Sciences (NRC, 2006) has stated that

> *Depending on the system examined, the estimated affinity of binding of TCDD (and related compounds) to the human AHR [aryl hydrocarbon receptor] is about 10-fold lower than that observed to the AHR from “responsive” rodent species and is comparable to that observed to the AHR from “nonresponsive” mouse strains.*

More recent studies have indicated that the difference may be even greater. Westerink et al. (2008) compared CYP1A activity (a cytochrome P450 enzyme) in rat H4IIE cells and human HepG2 cells for an extensive array of chemicals, including 2,3,7,8-TCDD and most dioxin-like PCBs. The investigators found that for PCB 126 (regarded as the most potent of the PCBs assigned TEFs), the rat was three orders of magnitude more sensitive to induction of liver enzyme activity than humans. Carlson et al. (2009) investigated whether the difference in relative potency of PCB 126 between rats and humans, as measured by induction of CYP1A1, was also true for other Ah receptor-regulated genes that could be important to toxic effects subsequent to Ah receptor binding. They found that 47 human genes responding in a dose-response manner consistent with the TEF concept were more than 100 times less sensitive than 79 similarly responding rat genes.

It should also be recognized that the relative potency (ReP) database used to derive TEFs is now over 10 years old; studies have been published since 2004 that may change the range and percentiles of RePs for many dioxin-like congeners including PCB 126 (Peters et al., 2006; Sutter et al.; 2010, Trnovec et al., 2013; van Ede, 2014; Larsson et al., 2015; van Ede et al., 2016). Van Ede et al. (2014, 2016) conclude that human in vitro-derived RePs for PCB 126, which has the highest TEF of the dioxin-like PCBs, are significantly lower (one to two orders of magnitude) than the present WHO-TEF, and a re-evaluation of this TEF for human health risk assessment is warranted.

Finally, summing TEF-based risks with risks posed by the non-dioxin-like congeners is in essence double-counting PCB risk, and was therefore not done in this BHHRA. The Aroclor mixtures upon which the PCB high risk and persistence CSF is based included dioxin-like PCBs (Cogliano, 1998; Mayes et al., 1998). Thus, the results of these whole animal studies represent the sum of the toxicities of all of the congeners present and their various mechanisms of actions and interactions, including both the dioxin-like and other toxicities. Several studies comparing these risk calculation methods have concluded that the evaluation of PCBs in fish tissue as total PCBs using the CSFs for PCB mixtures is sufficiently protective (Chaudhuri et al., 2003; Keenan and Samuelian, 2005; Bodishbaugh et al., 2003; Ruffle et al., 2016). The approach used in this BHHRA of calculating and presenting two separate sets of PCB risk and hazard estimates addresses the uncertainty associated with the different measures of toxicity while avoiding the problem of double-counting when dioxin-like and non-dioxin-like risk estimates are summed.

7.2.5 Tier 3 Toxicity Values

There is somewhat more uncertainty associated with the toxicity values from Tier 3 sources due to the variability of peer-review and consensus among scientists on the best estimate of toxicity. The majority of COPCs have Tier 1 or 2 toxicity values. A summary of the COPCs for which Tier 3 toxicity data were used is provided below.

Tier 3 Dose-Response Values Used in the BHHRA		
COPC	**Toxicity Factor Type**	**Source**
2,3,7,8-TCDD-TEQ	RfC, Oral CSF, URF	CalEPA
4,4-DDD	Oral RfD URF	PPRTV screening value CalEPA
4,4-DDE	Oral RfD URF	PPRTV screening value CalEPA
Arsenic, inorganic	RfC	CalEPA
Arsenic, organic	Oral RfD	ATSDR
Bromodichloromethane	URF	CalEPA
Chloroform	RfC	ATSDR
DRO	Oral RfD, RfC	PPRTV screening value
Mirex	Oral CSF, URF	CalEPA
MTBE	URF	CalEPA
Naphthalene	URF	CalEPA
Nickel	RfC URF	ATSDR CalEPA
Thallium	Oral RfD	PPRTV screening value
Vanadium	RfC	ATSDR

The uncertainty associated with the use of Tier 3 toxicity values is on the high side due to uncertainty in modes of action and adequacy of the toxicity data sets. Despite this conservatism, with the exception of 2,3,7,8-TCDD-TEQ in surface soil for the outdoor industrial worker, potential risks and hazards calculated using Tier 3 toxicity values are below 10^{-6} and an HI of 1. Thus, the impact of the uncertainty in the toxicity values used is not expected to be significant.

7.3 Exposure Assessment

The exposure assessment process is inherently uncertain, as assumptions must be made about individuals' behaviors and choices that bring them into contact with site media. Human behaviors are inherently variable, and as such, the assumptions used to characterize exposure are often conservative to ensure that risks to individuals with potential high-end exposures are not underestimated. Furthermore, it can be difficult to characterize exposures under future conditions. Because of uncertainty and variability in quantifying human behavior, the Superfund risk assessment process can lead to the use of less site-specific assumptions as a method to ensure conservatism.

Exposure assessment consists of three basic steps: (1) development of exposure scenario assumptions, (2) estimation of exposure point concentrations, and (3) estimation of human dose. The uncertainty associated with each of these steps, as well as the fish consumption pathway in particular, is discussed below.

7.3.1 Exposure Scenario Assumptions

Exposure scenarios in a risk assessment are selected to be representative of potential exposures to COPCs in media that human receptors may come into contact with based on current and reasonably foreseeable land use. These exposure scenarios were developed for a hypothetical receptor, but one that would represent the RME scenario. Therefore, exposure levels were assumed for these receptors that are greater than expected to typically occur in an actual population. It has been noted that the use of multiple health protective factors to address uncertainty can result in overestimating risk through compounding conservatism (Cullen, 1994; Burmaster and Harris, 1993; Nichols and Zeckhauser, 1988). Consequently, CTE scenarios were also explored to provide an estimate of exposures more likely to represent average exposures and put RME risk estimates into context.

When estimating human doses (i.e., intakes and external exposures) from potential exposure to various media containing COPCs, several assumptions are made. Uncertainty may exist, for example, in assumptions concerning the range of typical rates of ingestion, frequency, and duration of exposure, and bioavailability of the chemicals in the medium. Typically, when limited information is available to establish these assumptions or there are uncertainties associated with projecting future exposures, a conservative estimate of potential exposure is employed to ensure that a potentially exposed individual's risk is not underestimated. USEPA's default exposure assumptions for the RME scenario are intended to be conservative and representative of an individual on the upper end of the range of possible exposures (e.g., someone who frequently contacts affected environmental media at an upper-bound intake rate for many years). Moreover, it is often assumed that contact is with environmental media containing some of the highest chemical concentrations for the entire exposure duration used in the risk assessment, due to both statistical handling of the data and the assumption that concentrations do not change over time, despite natural recovery processes that tend to reduce environmental concentrations. Depending on the number of upper-bound assumptions employed, the probability of the potential exposure scenario occurring can be very low, as discussed further in Section 7.4.2.

This section discusses uncertainty associated with some of the key exposure assumptions selected for the BHHRA, and potential impact on risk estimates. Potential uncertainties associated with exposure frequency for the Anacostia River in the vicinity of the Waterside Investigation Area are described below. Consumption of fish represents the largest source of potential risk, and the associated uncertainties are discussed in Section 7.3.2.

Waterside Investigation Area Exposure Frequencies

The surface water and sediment exposure frequencies used in the BHHRA were developed taking into consideration the existing parks, walking trails, boat docks, and fishing activity within the Waterside Investigation Area, as well as potential improvements in these resources. However, it is possible that River use in the future could increase to a level higher than assumed in the BHHRA. As previously noted, direct contact with surface water and sediment are minor contributors to total risks and hazards when compared to potential fish consumption risks and hazards, as discussed below. Therefore, an increase in exposure frequencies for surface water and sediment is unlikely to result in changes to the conclusions of this BHHRA.

7.3.2 Fish Consumption Pathway

A number of parameters are used to estimate risk from consumption of fish, including consumption rate, species, body parts consumed, fraction ingested from the site, preparation and cooking methods, and years of fishing at the site. In selecting appropriate fish consumption rates, USEPA guidance (USEPA, 1989b, 2011) discusses the importance of considering site-specific factors, including water quality, public access, abundance of desirable species, and availability of other desirable water bodies, as well as characteristics of the angling population. Some of the major areas of uncertainty associated with key variables for assessing risk from consumption of fish, and implications for risk results, are discussed below.

7.3.2.1 Fish Consumption Rate

Data from angler surveys that included the Anacostia River were used to characterize fishing practices and consumption behaviors of anglers who fish at the River. Using these data instead of default assumptions or studies of other water bodies reduces uncertainty in the estimated fish consumption rates. However, as these studies were not conducted for the purpose of estimating fish consumption rates for use in human health risk assessment, there is some uncertainty in the reliability of the data for estimating long-term consumption rates.

Based on Site-specific survey data, RME and CTE fish consumption rates of 20 and 10 grams per day (g/day), respectively, were estimated for the adult recreational angler who eats his or her catch from the Waterside Investigation Area. Although there is currently a fish consumption advisory, it is possible that fish consumption rates would increase in the event the advisory is lifted. Additional improvements in the River could also lead to increased fish consumption in the future. Therefore, to provide perspective on these fish consumption rates, several alternate fish consumption rates are discussed below.

- **7.5 g/day,** which is equivalent to a one half-pound fish meal per month. This rate has been used at other sediment sites to provide risk information to the public and decision-makers on potential risks associated with consumption of various types of recreationally caught fish/crabs (e.g., Lower Duwamish Waterway). One meal per month is also a common target level of consumption used in setting consumption advisories.
- **22 g/day**, which is the fish/shellfish consumption rate used by USEPA to derive water quality criteria protective of the general public, as well as the average sport angler (USEPA, 2014b). The 22 g/day rate is based on per capita intake of freshwater and estuarine finfish and shellfish by the general population and represents the 90th percentile of US freshwater and estuarine finfish and shellfish consumption by the general population based on the 2003 to 2010 National Health and Nutrition Examination Survey (USEPA, 2014b).
- **32 g/day**, which is used by DOEE and Maryland Department of the Environment (MDE) to set fish consumption advisory levels that allow for a one half-pound fish meal per week.
- **65 g/day**, which is the 98th percentile rate reported by DC area anglers (Gibson and McClafferty, 2005). This corresponds to eating two self-caught fish meals per week year-round.

pepco
An Exelon Company

The alternate rates are summarized in the following table, including the corresponding number of fish meals per year (assuming a fish meal equates to a conservative half-pound of fish) and the ratio of the alternate rate to the rate used in this BHHRA for the RME adult angler.

Fish Ingestion Rates – Adult Angler			
Ingestion Rate (g/day)	**Fish Meals per Year**	**Basis**	**Ratio of Alternate Rate to BHHRA RME Rate**
7.5	12	One fish meal per month	0.4
10	*16*	*BHHRA CTE rate*	*0.5*
20	*32*	*BHHRA RME rate*	*1*
22	35	90th percentile of US freshwater & estuarine finfish and shellfish consumption by the general population	1.1
32	52	Advisory rate of one fish meal per week	1.6
65	104	98th percentile of DC area anglers consuming fish	3.25

Using the alternative consumption rates, potential risks from fish consumption could be less than the risks calculated in this BHHRA to as much as 6.5-fold higher (taking into account the site-specific fraction ingested factor of 0.5 as discussed in Section 7.3.2.3). If the fish consumption were to increase to one meal per week (32 g/day) potential risks and hazards could increase by 60%. Potential risks for an adult/young child angler would increase (from $4x10^{-4}$ to about $6x10^{-5}$), but would still be within the risk range. The HI would continue to exceed one. Therefore, the increase would not substantially impact the conclusions of this BHHRA.

The consumption rate of 65 g/day is based on the Gibson and McClafferty survey. However, it should be noted that the survey was conducted in 2004 by Virginia Tech researchers during warm weather months when fishing is highest and represents fish consumption from both the Potomac and Anacostia Rivers; both of these factors likely lead to overestimates of consumption of Anacostia River fish or the Waterside Investigation Area. An analysis of the potential risks/hazards for a high-end consuming angler for whom a large fraction of his or her diet is Anacostia River fish is discussed in Section 7.3.2.2, below.

7.3.2.2 High-End Consuming Angler Scenario

Based on the survey results presented in Gibson and McClafferty (2005), some anglers supplement a sizeable fraction of their diet with river fish. An analysis of a high-end consuming angler who fishes year-round and consumes two fish meals per week of Anacostia River fish is presented below. As noted in Section 7.3.2.1, the consumption rates based on the survey may be overestimated due to upward biases in the survey. Potential risks/hazards for the high-end consuming angler were calculated using a multiplier from the recreational risks/hazards and are summarized below.

Parameter	**Recreational Angler**	**High-End Consuming Angler**	**Recreational Consumption to High-End Consumption Multiplier**
RME Adult			
Consumption Rate (g/day)	20	65	3.25
Fraction of Diet[a]	0.5	1	2
		Overall:	**6.5**
RME Child			
Consumption Rate (g/day)	7	21	3
Fraction of Diet	0.5	1	2
		Overall:	**6**
Combined RME Adult/Child			**6.38**[b]

Notes:
[a] Fraction of mixed fish diet from Waterside Investigation Area.
[b] Weighted average assuming 6 years as a child and 6.5 years as an adult. Used as multiplier for potential carcinogenic effects.

The total risks/hazards for the high-end consuming angler who consumes a mixed fish diet are summarized in the following table along with the results for the recreational angler for comparison. Cancer risks are shown for the young child/adult and noncancer hazards for the young child angler.

Cumulative Risks/Hazards for Consumption of Fish (RME)				
Receptor	Cancer (Adult/Young Child)		Noncancer (Young Child) [a]	
	High-end	Recreational	High End	Recreational Young Child
Anacostia River [b]				
Upper Anacostia (Total PCBs)	2.7E-04	4.2E-05	19.2	3.2
Upper Anacostia (PCB-TEQ)	1.4E-04	2.2E-05	4.4	0.73
Background Area [b]				
Upstream Non-Tidal Anacostia (Total PCBs)	4.3E-05	6.7E-06	3.7	0.61
Upstream Non-Tidal Anacostia (PCB-TEQ)	5.0E-05	7.9E-06	3.7	0.61
Regional Reaches [b]				
Lower Anacostia (Total PCBs)	4.5E-04	7.1E-05	28	4.7
Lower Anacostia (PCB-TEQ)	5.8E-04	9.1E-05	18	3.0
Lower Potomac (Total PCBs)	3.9E-04	6.1E-05	14	2.3
Lower Potomac (PCB-TEQ)	4.1E-04	6.5E-05	7.2	1.2
Upper Potomac (Total PCBs)	1.1E-03	1.8E-04	84	14
Upper Potomac (PCB-TEQ)	1.6E-03	2.5E-04	55	9.1

Notes:
Blue highlighting indicates that cumulative risk exceeds 10^{-6} but is less than or equal to 10^{-4}.
Yellow highlighting indicates that cumulative risk exceeds 10^{-4} or the target endpoint HI exceeds 1.
[a] Highest target endpoint HI.
[b] Includes consumption of a mixed fish diet. Upper Anacostia encompasses the Waterside Investigation Area (**See Figure 3-7**).

As shown, the estimated total risks/hazards for the high-end consuming angler are 6- to 6.5-fold higher than for the recreational angler. Potential cancer risks and noncancer hazards for the high-end consuming angler exceed USEPA's risk thresholds in all reaches, except for cancer risk for the Upstream Non-Tidal Anacostia River reach. The highest potential total PCB risks for the high-end consuming angler are in the Upper Potomac, the same as for the recreational angler.

7.3.2.3 Fraction Ingested for Fish

There is uncertainty in the RME assumption that half of the recreational angler's self-caught fish comes from the Waterside Investigation Area and half comes from other locations. Similarly, there is uncertainty in the CTE assumption that 25% of the recreational angler's catch comes from the Waterside Investigation Area. However, given the relatively small portion of river shoreline adjacent to the Site relative to the length of the Anacostia River (less than 6%), the presence of undergrowth limiting access in the vicinity of the Site, and the proximity of other fishable water bodies, including the upstream reaches in Maryland, the Potomac River, and Chesapeake Bay, it is likely that even those anglers who live near the Study Area fish at multiple water bodies in the surrounding area. Thus, use of fraction ingested factor of 50% for the RME and 25% for the CTE is reasonable.

7.3.2.4 Cooking Loss

Loss of hydrophobic COPCs upon cooking is a recognized phenomenon that can have a significant effect on the calculated COPC exposure dose from tissue consumption by humans. Losses vary with cooking method (e.g., broil, bake, pan fry), preparation method (e.g., trimmed/untrimmed, skin-on/skin-off), and species. Based on available guidance and literature on chemical loss of PCBs and pesticides from preparation and cooking of fish, the following cooking loss factors were derived in **Attachment D** based on a literature review:

COPC	Number of Studies [a]	Number of Data Points	Cooking Loss Factor	
			10th Percentile RME	Median CTE
Total PCBs	14	79	0.13	0.30
Dioxins, furans, and coplanar PCBs	4	12	0.29	0.48
DDx	10	70	0.10	0.32

Notes:
DDx = dichlorodiphenyltrichloroethane, dichlorodiphenyldichloroethylene, and dichlorodiphenyldichloroethane
[a] See **Attachment D** for study references.

The studies on loss of PCBs from fish tissue due to preparation and cooking report little to no loss to as much as 74% loss. However, most of the studies reported some loss, with a median of 30%. For dioxins, furans, and coplanar PCBs, cooking loss ranged from 28% to 63%. Median losses by cooking method ranged from 29% (boil/poach) to 57% (bake/roast), with an overall median of 48%. For DDx, cooking loss ranged from 3% to 80%. Median losses by cooking method ranged from 22% (boil/poach) to 45% (smoke), with a median of 32% when all DDx data are combined regardless of cooking method. Cooking loss for other pesticides was assumed to be similar to DDx. Therefore, the DDx cooking loss factors were applied to the remaining pesticide COPCs.

The amount of chemical mass loss varied within and between studies, which is likely due to a variety of factors, such as cooking time, temperature, tissue preparation (skinning and trimming) and fillet geometry, lipid content, initial chemical concentration, analytical method, and extraction efficiency, which are not consistently controlled for across the various studies. Based on the available data, the use of the 10th percentile cooking loss value for the RME and the median cooking loss value for the CTE is reasonable and conservative, and the cooking loss parameter is not expected to be a major source of uncertainty in the BHHRA.

7.3.2.5 Consumption of Other Fish Species

The BHHRA assumed that the angler consumes a mixed diet comprising multiple species that reside in the Anacostia River (i.e., American eel, catfish, carp, largemouth bass, northern snakehead, and sunfish). The species included in the EPC for each River reach was based on the available samples for that reach and was calculated as a pooled EPC combining the samples without assigning any percentages to specific species. For example, in the Upper Anacostia Reach, there are seven available fish fillet samples consisting of brown bullhead, blue catfish, carp, channel catfish, largemouth bass, northern snakehead, and sunfish. The EPC was calculated as the 95% UCL of these seven samples.

However, the species consumed by anglers varies and depends on a variety of factors, such as:

- Season of the year
- Water quality characteristics, including temperature, dissolved oxygen, and turbidity
- Fishery characteristics, including habitat and species abundance
- Angler characteristics, including fishing method, bait, and species preferences

Some anglers have preferences for particular species and may limit their consumption to those species; it is also possible that different ratios of the available species are consumed. This section addresses the potential risks from alternate consumption practices, such as single-species diets and alternate mixed fish diets.

The table below presents the total cancer risks and noncancer hazards (calculated in **Attachment H**) for the RME angler based on a range of potential consumption practices. For illustrative purposes, estimated risks and hazards are based on total PCBs and are shown for the Upper Anacostia River, which includes the Waterside Investigation Area. Seven fish fillet samples are available for the Upper Anacostia, as noted above.

Potential Risk and Hazard for Total PCBs for Baseline and Alternate Fish Diets				
Fish Diet	**RME Angler (Cancer) Upper Anacostia**		**RME Angler (Noncancer) Upper Anacostia**	
	Child	**Adult**	**Child**	**Adult**
Baseline Diet				
Mixed species diet (7 samples)	1.1E-05	2.2E-05	3.2	2.0
Alternative Diets				
100% catfish (2 samples)	7.8E-06	1.6E-05	2.3	1.4
100% carp (1 sample)	2.1E-05	4.2E-05	6.1	3.7
100% largemouth bass (1 sample)	3.7E-06	7.5E-06	1.1	0.65
100% sunfish (1 sample)	1.3E-06	2.6E-06	0.38	0.23
100% northern snakehead (1 sample)	1.5E-06	3.1E-06	0.45	0.27
50% catfish & 50% largemouth bass (3 samples)	5.7E-06	1.2E-05	1.7	1.0

For the catfish single-species diet, the higher of the channel and blue catfish concentration (channel catfish sample) was used to represent catfish in the alternative diet evaluation. For the other single-species diets, the detected concentration was used. For the mixed catfish/largemouth bass diet, the detected concentration in largemouth bass was averaged with the maximum catfish concentration. The estimation of potential risks for alternate diets are based on very small data sets, one each for carp, largemouth bass, sunfish, and northern snakehead, and two for catfish. Therefore, the same uncertainties discussed in Section 7.1.2 regarding the size (and age) of the fish tissue data set apply to the analysis of single-species diets presented here.

The baseline mixed diet falls within the range of the alternate diets. The risks and hazards associated with a 100% catfish diet or a mixed catfish/largemouth bass diet are lower than the baseline mixed fish diet. As discussed in Section 7.3.2.1, angler survey data indicate a preference for catfish. Therefore, the baseline mixed fish diet may overestimate potential risks and hazards to most anglers.

7.3.2.6 Fish Tissue Type Consumed

The BHHRA assumed that only the fish fillet was consumed, as this is the body part typically consumed by most anglers (USEPA, 2000; Gibson and McClafferty, 2005). However, some anglers may consume the whole fish or additional parts besides just the fillet (e.g., use the head and carcass in soup or stock).

Because whole body concentrations for lipophilic chemicals are usually higher than fillet concentrations, risks may be underestimated for those who consume more than just the fillet. Whole body fish tissue data are not available from the Pinkney data sets (Pinkney, 2017) for the Upper and Lower Anacostia River or the Upper and Lower Potomac River. Samples of fillet and whole body fish tissue were collected from the Upstream Non-Tidal Anacostia. The ratio of whole body to fillet concentrations for total PCBs in those samples ranged from 3.3 to 13.6, as follows, by species:

Species	Ratio of Whole Body to Fillet Concentration for Total PCBs			
	Number of Samples	Minimum Ratio	Maximum Ratio	Mean Ratio
Largemouth bass	19	3.4 to 1	11.7 to 1	5.7 to 1
Smallmouth bass	6	4.2 to 1	9.2 to 1	5.7 to 1
Striped bass	3	3.3 to 1	4.5 to 1	3.8 to 1
Northern snakehead	1	13.6		

The ratio of whole body to fillet concentrations reported in the literature varies by species and lipid content, ranging from 1 to 1 to 1.5 to 1 for fish with high lipid content (e.g., lake trout, carp) to 3 to 1 to 5 to 1 or more for species with low lipid content (e.g., bass, pike, perch) (Skinner et al., 2009; Burman and Rygwelski, 2006; Amrhein et al., 1999). Thus, depending on species, estimated whole body fish consumption risks may be higher than the fillet-based risks estimated in the BHHRA.

7.3.2.7 Consumption of Other Biota

It is possible that other biota present in the Anacostia River besides fish, such as turtles, ducks, frogs, etc., are consumed.[25] However, due to the lack of data on consumption of other aquatic species or waterfowl, this potential exposure pathway was not evaluated quantitatively in the BHHRA. The angler surveys revealed little crabbing or crab consumption on the Anacostia River. Based on available data, fish are the primary target of Anacostia River anglers. Not evaluating consumption of other biota in the BHHRA is unlikely to have resulted in the omission of a significant route of exposure to this population.

7.3.3 Estimation of Exposure Point Concentrations

The data used to calculate the EPCs were assumed to be representative of general area conditions. Sample locations were selected based on several factors, including prior knowledge of source areas,

[25] Due to low salinity levels in the River in the vicinity of the Site, crabs are not expected to be present (NOAA, 2012).

potential migration patterns, and ensuring adequate spatial coverage. Nevertheless, due to spatial and temporal variability, as well as sampling and analytical limitations, there is uncertainty in the EPCs used to estimate current conditions in environmental media. Key uncertainties are discussed below.

Exposure to COPCs is best estimated by the arithmetic mean concentration (USEPA 1989a, 2002b). Because of the uncertainty associated with estimating the true average concentration, USEPA's guidance states that "the 95 percent upper confidence limit of the arithmetic mean should be used for this [the average] variable" (USEPA, 2002b). This statistic provides a conservative upper-bound estimate of the average chemical concentration in an environmental medium. The EPCs used in the BHHRA represent the lower of either the maximum detected concentration or the 95% UCL of the arithmetic mean for the RME scenario and the mean for the CTE scenario (USEPA, 2002b). The use of the UCL (or maximum detection) reduces uncertainty that EPC will understate the true average concentration.

Fish Tissue EPCs

There is substantial uncertainty in the tissue EPCs due to limited sample sizes (e.g., six in the Lower Anacostia and seven in the Upper Anacostia). The use of composite tissue samples, which are comprised of multiple individual specimens, addresses some of the uncertainty associated with small sample sizes. However, the representativeness of the fish tissue EPCs remains uncertain due to the limited tissue data set, and the age of the data set in view of the fact that fish tissue concentrations have been declining over time and the data set does not reflect subsequent improvements, such as may be attributable to recent major reductions in CSOs discharges to the Anacostia River.

Fringe Sediment EPCs

There is uncertainty in the characterization of fringe surface sediment data for the evaluation of direct contact exposures. Per the approved work plan, the top 6 inches of fringe sediment were assumed to be the point of exposure for human contact with sediment. However, it is possible that sediment at depths greater than the top 6 inches or within the deeper part of the channel may be transported to fringe surface sediment as a result of erosion, currents, and/or mixing processes. The concentrations of some COPCs in deeper sediment and farther into the channel are not substantially different from or are generally lower than concentrations in fringe surface sediment. For some other COPCs, concentrations in deeper sediments are generally higher than at the surface. For COPCs with concentrations that are greater at depth, the use of the fringe surface sediment data to estimate current and future EPCs may underestimate direct contact risks if the deeper sediments migrate to the fringe surface sediment in the future. On the other hand, for COPCs with concentrations that change little or are lower at depth, the use of fringe surface sediment data does not underestimate potential direct contact risks.

Soil and Groundwater EPCs

Soil and groundwater sampling at the Site were extensive and included delineation to RBSLs. Based on the large sample sizes and sampling areas, the uncertainty associated with soil and groundwater EPCs is considered low. It was assumed that the future outdoor industrial worker and the hypothetical future recreational visitor are exposed to soils that are currently located at a depth of 0 to 1 foot bgs or immediately below existing slab. However, it is possible that in the future, subsurface soils could be brought to the surface, making them accessible to contact by these receptors, as discussed below.

A review of the EPCs for surface soil (**Table 5-10**) and soil (0 to 16 feet bgs, **Table 5-12**) indicates that for the hypothetical future park land/green space area, soil EPCs are the same as surface soil EPCs (where the maximum detected concentration was from surface soil) or lower than surface soil EPCs (due to a larger data set and calculation of UCL), with one exception. The soil EPC for manganese is just under 2-fold higher than the surface soil EPC; however, the HIs associated with manganese are less than 0.05, and even if doubled, would not exceed 1. Therefore, in this area, potential risks and hazards for both receptors would be the similar to those calculated in the BHHRA based on surface soil EPCs.

Similarly, over 50% of soil EPCs in the remaining areas (outdoor industrial worker exposure only) are the same as or lower than surface soil EPCs. About 10% of the soil EPCs ranged from 1.1 to 1.7 times higher than the surface soil-only EPCs. About 30% of the soil EPCs ranged from about 2 times higher than the surface soil EPCs to about 15 times higher, and only 5% of soil EPCs were more than 15 times greater than surface soil EPCs. No soil EPCs were more than 20 times higher than surface soil EPCs. The majority of cases where soil EPCs were greater than 2 times the surface soil EPCs were for PAHs or DRO in the warehouse and laydown area, the salvage yard and waste storage area, the stores and maintenance area, the offices and parking lot area, and the transformer shop. Therefore, in these areas, it is possible that if subsurface soils are brought to the surface, potential risks and hazards associated with PAHs and DRO could be more than 2 times higher than predicted in the BHHRA based on surface soil EPCs. It should be noted, however, that if subsurface soils were brought to the surface in the future, it would likely be in combination with other Site work and re-grading that would result in mixing the excavated soil, such that the use of current EPCs to model this hypothetical situation is highly uncertain.

It is assumed that the EPCs used in the risk assessment based on current conditions will remain constant for the assumed exposure duration for an industrial or recreational scenario; this is typically a period of 25 to 26 years. However, it is well known that chemicals in the environment are subject to natural attenuation and biodegradation processes. Organic chemicals are naturally degraded in the environment by a variety of processes (i.e., photodegradation, microbial activity, hydrolysis, etc.). At sediment sites, deposition of cleaner sediment is an important process by which constituent concentrations in surface sediment are reduced over time. USEPA recognizes the validity and utility of natural attenuation and biodegradation as a remedial option and has published guidance for its site-specific implementation (USEPA, 1997b; 2005a). Environmental half-lives vary for specific chemicals based on environmental conditions (i.e., presence of bacteria, pH, exposures to sunlight and oxygen), and there are respected literature sources of such information. However, environmental degradation has not been accounted for in the calculation of potential risks and hazards in the Study Area. Current concentrations in Study Area media (soil, groundwater, fringe surface sediment, surface water, and fish tissue) were assumed to remain unchanged into the future for the exposure durations evaluated in the BHHRA (i.e., up to 26 years).

7.3.4 Estimation of Exposure Dose

7.3.4.1 Soil and Fringe Surface Sediment

As discussed in Section 5.4, AAFs/RBAs are used in risk assessment to account for absorption differences between humans exposed to substances in environmental situations and experimental animals in the laboratory studies used to derive dose-response values. Support for use of AAFs/RBAs is provided in USEPA guidance (USEPA, 1989a).

Oral bioavailability is a measure of the degree to which a chemical may be systemically absorbed following ingestion, and dermal bioavailability is a measure of the degree to which a chemical may absorb through the skin and into the blood stream. Some chemicals are absorbed almost completely (100% bioavailability) when ingested in pure form. Other chemicals may pass through the body largely unabsorbed. Thus, the amount that is absorbed is both uncertain and variable. As a result, USEPA's default assumptions regarding absorption are conservative and intended to apply to most sites and exposure conditions. Key factors that influence bioavailability include:

- Physical characteristics of the chemical. In general, as the lipophilicity of a chemical increases, its absorption across the gastrointestinal tract increases.
- The rate at which chemicals dissociate from soil or sediment in the gut. Soil/sediment-bound chemicals, particularly inorganics, are usually absorbed to a lesser degree than chemicals in pure form. The reduced absorption is a result of hydrophobic attraction between the chemical and soil matrix.
- Soil/sediment aging. Aging results in the migration of the chemical into the interior of the soil or sediment particle so that less remains on the exterior surface. This sequestration or aging of the chemical over time reduces the accessibility of a chemical when ingested or dermally contacted by

humans because the chemical is bound in the soil/sediment matrix and not extracted by stomach acid or skin moisture.

Therefore, for chemicals that have been immobilized in soil or sediment by the aging process, the total concentration of the chemical may be a poor indicator of its current relative toxicity. The assumption of 100% oral bioavailability of chemicals in aged soil or sediment is unlikely and has likely resulted in an overestimation of potential risks from incidental ingestion of soil and fringe surface sediments.

While there is uncertainty associated with the use of default DAFs for evaluating dermal exposures, the assumptions and method used are more likely to overestimate than underestimate potential exposures. Further, potential dermal contact risks associated with fringe surface sediment and soil are low (near or below 10^{-6} cancer risk and below an HI of 1). Therefore, the use of the default approach has minimal impact on the conclusions of the BHHRA.

7.3.4.2 Surface Water

The quantification of potential noncancer hazards and cancer risks associated with the surface water pathway followed Exhibit 1-2 in the USEPA RAGS Part E guidance (2004a). Specifically, if dermal assessment was not recommended in USEPA RAGS Part E (2004a), no further evaluation of the dermal pathway was conducted for that COPC. Dermal assessment is not recommended for chemicals with a very large or very small octanol-water partition coefficient value. These chemicals are considered to be outside of the "Effective Prediction Domain," which means that an appropriate K_p value cannot be predicted by the statistical model (USEPA, 2004a). Based on the guidance, the dermal contact pathway associated with 2,3,7,8-TCDD-TEQ, total PCBs, and 4,4-DDT in surface water is considered to be negligible. Given the relatively low concentrations and potential risks/hazards associated with the incidental ingestion pathway, any potential exposure via dermal contact is expected to be negligible.

7.4 Risk Characterization

The potential risk of adverse human health effects is characterized based on estimated potential exposures and potential dose-response relationships. The following areas of uncertainty are introduced in this phase of the risk assessment: the evaluation of potential exposure to multiple chemicals, the combination of upper-bound exposure estimates with upper-bound toxicity estimates, the risks to sensitive populations, and the characterization of background risks.

7.4.1 Risk from Multiple Chemicals

Once potential exposure to and potential risk from each COPC are estimated, the total upper-bound potential risk posed for each receptor is determined by combining the estimated potential health risk from each of the COPCs. Presently, potential carcinogenic effects are added unless evidence exists indicating that the COPCs interact synergistically (a combined effect that is greater than a simple addition of potential individual effects) or antagonistically (a combined effect that is less than a simple addition of potential individual effects) with each other.

For noncarcinogenic effects, the HI should only be summed for chemicals that have the same or similar target endpoints (USEPA, 1989a). The target endpoint is defined as the most sensitive noncarcinogenic health effect used to derive the RfD, RfC or other suitable toxicity value (USEPA, 1989a). Again, there is little evidence to suggest whether those COPCs associated with a common target endpoint are additive, synergistic, antagonistic, or independent in terms of mechanism of action. Whether assuming additivity leads to an underestimation or overestimation of risk is unknown. In this risk assessment, it was assumed that HQs from COPCs with the same target endpoint are additive (e.g., all the HQs from the COPCs with neurological effects are added together). As shown in **Table 4-1**, there is limited overlap in the target endpoints for the COPCs in this BHHRA, suggesting this is a minor area of uncertainty.

Further, PCBs are the dominant COPC driving exceedances of the noncancer target HI of 1. Total PCBs contribute over 99% of the cumulative hazard for the outdoor industrial worker in the transformer shop area (the only area with an HQ greater than 1 for PCBs in soil). Total PCBs contributes approximately 85% of the cumulative noncancer hazard for the angler receptors that consume fish (all age groups) and contact fringe surface sediment and surface water (adult and older child only) in the Anacostia.

7.4.2 Combination of Several Upper-Bound Assumptions

Generally, the goal of a risk assessment is to estimate an upper-bound potential exposure and risk. Most of the assumptions about exposure and toxicity used in this evaluation are representative of statistical upper-bounds or even maxima for each parameter. The result of combining several such upper-bound assumptions is that the final estimate of potential exposure or potential risk is extremely conservative (health-protective).

This is best illustrated by a simple example. Assume that potential risk depends on three variables (soil consumption rate, exposure duration, and CSF). The mean, upper 95% bound and maximum are available for each variable. One way to generate a conservative estimate of potential risk is to multiply the upper 95% bounds of the three parameters in this example. Doing so assumes that the 5% of the people who are most sensitive to the potential carcinogenic effects of a COPC will also ingest soil at a rate that exceeds the rate for 95% of the population and will do so at the same residence for the number of years that represents only 5% of the population. The consequence of combining these assumptions is that the estimated potential risk is representative of 0.0125% of the population (0.05 x 0.05 x 0.05 = 0.000125 x 100 = 0.0125%). Put another way, these serial assumptions overestimate risks for 99.99% of the population or 9,999 out 10,000 people. Thus, the majority of people will have a much lower level of potential risk. The very conservative nature of the potential risks estimated by the risk assessment process is not generally recognized. In reality, the estimates are more conservative than outlined above because more than three upper 95% assumptions are usually used to estimate potential risks.

Alternatively, if the CTE estimate is considered, whereby a single upper 95% assumption of the cancer slope factor is combined with average (50th percentile) assumptions for exposure point concentration and soil ingestion rate, the resulting estimates of potential CTE risk still over-predict the risk to nearly 99% of the potentially exposed population (0.05 x 0.5 x 0.5 = 0.0125 x 100 = 1.25%). This is a conservative and health-protective approach that substantially overestimates the “average” level and even the reasonable maximum level of potential risk.

The risk assessment approach used here employed upper 95% bounds or maxima for most RME exposure and toxicity assumptions. Thus, it produces estimates of potential risk two to three orders of magnitude greater than the risk experienced by the average member of the potentially exposed populations. The CTE scenarios used average estimates of exposure and concentration where possible, but still used the conservative toxicity values, including the use of the upper-bound CSF for PCBs rather than the central-estimate slope factor; thus, even the CTE risk estimates are likely to overestimate risk.

7.4.3 Risks to Sensitive Populations

The health risks estimated in the risk characterization apply to the receptors whose activities and locations were described in the exposure assessment. Some people will always be more sensitive than the average person, and therefore will be at greater risk. Dose-response values used to calculate hazard and risk, however, are frequently derived to account for additional sensitivity of subpopulations (e.g., the uncertainty factor of 10 used to account for intraspecies differences). In addition, as previously discussed, the selection of the study upon which a cancer slope factor is based often involves the most sensitive species and tumor site. Therefore, it is unlikely that this source of uncertainty contributes significantly to the overall uncertainty of the risk assessment.

7.4.4 Characterization of Background

As discussed in Section 6.4, fish consumption risks exceed the target HI of 1 due to PCBs throughout the Anacostia River, including the upstream non-tidal portion of the River. These findings suggest that there are multiple sources of PCBs in the Anacostia River, including upstream of the tidal influence of the Waterside Investigation Area. As stated in guidance, "the presence of high background concentrations of hazardous substances, pollutants, and contaminants found at a site is a factor that should be considered in risk assessment and risk management" (USEPA, 2002e).

There is uncertainty in the characterization of background risks posed by PCBs in fish tissue. A general decline in PCB tissue concentrations over time has been observed in the reach of the Anacostia River within the District (Pinkney, 2017). In summary, while there is some uncertainty in the extent to which background contributes to the Study Area risk, the inclusion of background conditions in the risk assessment results means that the calculated risk cannot be attributed solely, or even primarily, to Site-related constituents.

7.5 Summary of Uncertainty in BHHRA

The assumptions made in the various steps of the BHHRA for the Study Area introduce uncertainty in the results. While the use of assumptions could potentially lead to underestimates of potential risk, the use of numerous conservative (i.e., protective of human health) assumptions, as was done here, more likely overestimates potential risks. Assumptions regarding media concentrations, exposures, and toxicity used in this BHHRA were generally representative of statistical upper-bounds. The result of combining several such upper-bound assumptions is that the final estimate of potential exposure and/or potential risk/hazard is very conservative, and may lie at the extreme upper end, or even above, the distribution of risks in the actual exposed population. Elevated levels of PCBs are present in fish tissue throughout the region, suggesting that a significant portion of the estimated risk is actually a reflection of regional conditions. The results of the BHHRA for the Study Area should be carefully interpreted considering the uncertainty and conservatism associated with the analysis, especially when risk management decisions are made.

8 Summary and Conclusions

This BHHRA was performed for the Study Area located in Washington, DC, in accordance with the approved Risk Assessment Work Plan and Addendum (AECOM, 2012, 2016d) and applicable guidance. The assessment utilized relevant data from Pepco's Landside and Waterside RI activities conducted between January 2013 and July 2018, and DOEE's ARSP (TetraTech, 2018). Based on a Site-specific CSM that considered potential sources, migration pathways, and affected media, the potential routes of exposure to COPCs were identified taking into consideration current and future land uses. Health-protective assumptions and approaches were used to provide a conservative assessment of potential human health risks. The results of the BHHRA will be used to help inform the need for any additional evaluation and/or remedial action at the Study Area.

8.1 Summary of BHHRA for the Study Area

This section summarizes the approach and results of the BHHRA, which was conducted in accordance with the four-step paradigm recommended by USEPA (1989a):

1. Data evaluation and hazard identification
2. Toxicity assessment
3. Exposure assessment
4. Risk characterization

A summary of each of the four steps is presented below.

8.1.1 Data Evaluation and Hazard Identification

The soil, groundwater, sediment, and surface water data collected between 2013 and 2018 in accordance with the DOEE-approved RI/FS Work Plan and addenda (AECOM, 2012, AECOM, 2014a, AECOM, 2014b, AECOM, 2016e) were used in the BHHRA. The RI samples were analyzed for a broad range of chemicals, including inorganics, PCBs, dioxins and furans, pesticides, TPH, VOCs, and SVOCs. The BHHRA data set was augmented with composite samples of fish tissue collected in the Anacostia River under separate DOEE programs. Additionally, the BHHRA fringe surface sediment data set was augmented with fringe surface sediment data collected by DOEE for the ARSP. The combination of these field investigations provided the following BHHRA data set:

Matrix	Number of Abiotic Media Samples for the BHHRA	
	Study Area	Background
Surface soil (0-1 ft bgs)	291	19
Subsurface soil (1 to 16 ft bgs)	623	19
Groundwater	125	14
Fringe surface sediment (0 to 6 inches)	42	42
Surface water	10	10

Species (fillet)	Number of Biotic Media (Tissue) Samples for the BHHRA				
	CSX Bridge to MD State Line	Regional			Background
	Upper Tidal Anacostia	Lower Tidal Anacostia	Lower Potomac	Upper Potomac	Upstream Non-Tidal Anacostia
American eel	--	1	2	1	--
American shad	--	--	1	--	--
Brown bullhead	1	--	1	1	--
Catfish (blue)	1	1	1	--	--
Catfish (channel)	1	1	1	1	--
Common carp	1	1	1	1	--
Largemouth bass	1	1	1	1	19
Northern snakehead	1	--	--	1	1
Smallmouth bass	--	--	--	--	6
Striped bass	--	--	--	1	3
Sunfish	1	1	1	1	--
White perch	--	--	--	1	--
Total	**7**	**6**	**9**	**9**	**29**

The RI data underwent review and validation in accordance with the QAPP and USEPA guidance, and over 99% were found to be reliable and acceptable for use in risk assessment and remedial decision-making.

Based on a conservative screening process, 43 COPCs were identified for further evaluation in the BHHRA. For soil in the Landside Investigation Area, the COPCs included 2,3,7,8-TCDD-TEQ, several inorganics, PCBs, PAHs, and DRO. For groundwater, the only potentially complete exposure pathways identified were vapor intrusion from groundwater into an excavation trench for a construction worker, vapor intrusion from groundwater into the air of a building under a hypothetical future scenario, and discharge to the Anacostia River. Several VOCs, including MTBE, trichloroethylene, tetrachloroethylene, and vinyl chloride, were identified as COPCs in groundwater for the excavation trench pathway. Trichloroethylene, tetrachloroethylene, chloroform, and vinyl chloride were identified as COPCs for the vapor intrusion to indoor air pathway. No exceedances of surface water criteria were identified for groundwater potentially discharging into the Anacostia River after taking into consideration conservative DAFs.

For the Waterside Investigation Area, the COPCs in fringe surface sediment included 2,3,7,8-TCDD-TEQ, several inorganics, PCBs, PAHs, and DRO. COPCs in surface water included 2,3,7,8-TCDD-TEQ, several inorganics, 4,4-DDT, and PCBs. COPCs in Upper and Lower Anacostia fish tissue included arsenic, mercury, pesticides, and PCBs. Of the COPCs identified for fish tissue in the Upper and Lower Anacostia, only arsenic and PCBs were also identified as COPCs for fringe surface sediment and surface water. It should also be noted that several of the chemicals identified as COPCs are also present in upstream, lateral, and atmospheric sources that contribute to the Anacostia River.

8.1.2 Dose-Response Assessment

The dose-response values used in the BHHRA were identified in accordance with USEPA guidance (USEPA, 2003a, 2013). Both cancer and noncancer dose-response values were identified for oral and inhalation exposures. USEPA's DAFs (USEPA, 2004a) were used to evaluate dermal exposures to COPCs in fringe surface sediment and soil.

The majority of dose-response values used in the BHHRA were obtained from the USEPA's primary source of toxicity values, which is the IRIS database (USEPA, 2018b). The selection of dose-response values for COPCs lacking Tier 1 toxicity values followed USEPA's hierarchy of alternative sources of toxicity values (USEPA, 2003a, 2013).

8.1.3 Exposure Assessment

Based on the CSM and consideration of current and future conditions in the Landside Investigation Area, contact with on-Site media is unlikely under the current scenario. Groundwater is not used for drinking water, and direct contact with soil is unlikely based on the limited Site access, tight security, and presence of pavement and/or soil cover across most of the Site. The existing operational and institutional controls in place will continue to provide effective exposure prevention measures in the future. However, in the unlikely event that conditions change in the future, it is possible that receptors may be potentially exposed to on-Site media. Eight exposure areas have been defined for soil and groundwater based on current Site use, as indicated below (see **Figure 3-1**):

- Hypothetical Future Park Land /Green Space
- Warehouse and Laydown Area
- Salvage Yard and Waste Storage Area
- Stores and Fleet Maintenance Area
- Offices and Parking Lot
- Substation #7
- Transformer Shop
- Vehicle Refueling Area

The Waterside Investigation Area was evaluated as one exposure area for direct contact exposures to fringe surface sediment and to surface water. The Upper Anacostia River (upstream of the CSX bridge to the Maryland state line), which includes the Waterside Investigation Area, was evaluated for potential exposure via consumption of fish. Four regional reaches were also evaluated for potential exposure via fish consumption, including the Lower Anacostia River, the Upper Potomac River (upstream of the 14th Street bridge), the Lower Potomac River (downstream of the 14th Street bridge, and the Upstream Non-Tidal Anacostia River background reach (north of the Maryland state line).

Based on the human health CSM developed for the Study Area, the following potential receptors and exposure pathways were identified for quantitative evaluation:

Landside Receptors:

- Current/future construction workers who may be exposed via incidental ingestion of and/or dermal contact with soil (0 to 16 feet bgs) via inhalation of fugitive dust derived from soil, and via inhalation of vapors from groundwater in an excavation trench.
- Future outdoor industrial workers who may be exposed via incidental ingestion of and/or dermal contact with surface soil and via inhalation of fugitive dust derived from surface soil.

- Future indoor industrial workers who may be exposed to VOCs in indoor air resulting from groundwater vapor intrusion, should a building be constructed in an area with volatile COCs in the future.
- Hypothetical future recreational visitors who may be exposed via incidental ingestion of and/or dermal contact with surface soil and via inhalation of fugitive dust derived from surface soil.

Waterside Receptors:

- Anglers who may be exposed via incidental ingestion of and dermal contact with fringe surface sediment and surface water, and via consumption of Upper Anacostia River fish.
- Swimmers and waders who may be exposed via incidental ingestion of and/or dermal contact with fringe surface sediment and surface water within the Waterside Investigation Area.
- Shoreline workers who may be exposed via incidental ingestion of and/or dermal contact with fringe surface sediment and surface water adjacent to the Site.

The BHHRA also included a screening-level evaluation of the potential impact of Site groundwater on the River by comparing estimated in-stream concentrations of chemicals detected in groundwater to applicable surface water screening levels.

Consistent with the approved Risk Assessment Work Plan and Addendum (AECOM, 2012, 2016d), the BHHRA evaluated both RME and CTE scenarios to provide information on a range of potential exposures and risks. Realistic but appropriately conservative exposure parameter values were selected to represent potential exposures under both current and future Site uses. Site-specific information on land uses, populations, and activities were considered in the identification of relevant exposure scenarios and representative parameter assumptions. This included review of available angler surveys to gather information on angler behaviors and consumption practices.

The lower of the 95% UCL of the arithmetic mean and the maximum concentration was used as the exposure point concentration for the RME scenarios, and the mean was used in the evaluation of the CTE scenarios. While PCBs were not detected in surface water, PCBs were conservatively included in the risk calculations for potential surface water exposures using the lowest reporting limit achieved as a proxy EPC.

8.1.4 Risk Characterization

The risk characterization results are discussed below for the Landside and Waterside Investigation Areas, as well as background and regional reaches. For each receptor, the cumulative carcinogenic risks are compared to the USEPA acceptable risk range of 10^{-4} to 10^{-6}. The cumulative noncancer hazards for each receptor are compared to the USEPA goal of protection of an HI of 1 (per target endpoint).

8.1.4.1 Landside Scenarios

The cumulative RME and CTE cancer risks and noncancer hazards for the landside receptors are summarized in the following table.

Landside Receptors – Cumulative Risks/Hazards				
Exposure Area	Cancer		Noncancer [a]	
	RME	CTE	RME	CTE
Current/Future Construction Worker (Adult)				
Hypothetical Future Park Land/Green Space	2E-08	8E-09	1	0.3
Warehouse and Laydown Area	4E-07	7E-08	3	0.5
Salvage Yard and Waste Storage Area	5E-07	1E-07	0.7	0.1
Stores and Fleet Maintenance Area	9E-08	3E-08	0.2	0.07
Offices and Parking Lot	4E-07	8E-08	0.8	0.2
Substation #7	3E-07	3E-08	0.5	0.08
Transformer Shop	2E-06	7E-07	1.6	0.5
Vehicle Refueling Area	4E-08	1E-08	0.2	0.08
Future Outdoor Industrial Worker (Adult)				
Hypothetical Future Park Land/Green Space	1E-06	1E-07	0.3	0.1
Warehouse and Laydown Area	2E-05	1E-06	1	0.2
Salvage Yard and Waste Storage Area	1E-05	1E-06	0.3	0.05
Stores and Fleet Maintenance Area	4E-06	4E-07	0.08	0.03
Offices and Parking Lot	3E-06	4E-07	0.03	0.01
Substation #7	2E-05	6E-07	0.3	0.02
Transformer Shop	2E-03	3E-05	124	8
Vehicle Refueling Area	1E-06	1E-07	0.03	0.01
Future Indoor Industrial Worker (Adult)				
Southern Boundary	2E-5	b	2	b
Northern Boundary	4E-6		0.005	
Downgradient Perimeter	1E-6		0.3	
MW05A	8E-7		0.1	

Landside Receptors – Cumulative Risks/Hazards				
Exposure Area	**Cancer**		**Noncancer [a]**	
Future Recreational Visitor (Older child/teen)				
Hypothetical Future Park Land/Green Space	7E-08	7E-09	0.04	0.009

Notes:
Blue highlighting indicates that risk exceeds 10^{-6} but is less than or equal to 10^{-4}.
Yellow highlighting indicates that risk exceeds 10^{-4} or the target endpoint HI exceeds 1.
[a] Highest target endpoint HI
[b] CTE scenario was not included for the screening level vapor intrusion evaluation.

The total potential carcinogenic risks for all Landside receptors are within or below the USEPA target risk range of 10^{-4} to 10^{-6} with the exception of the RME future outdoor industrial worker exposed to surface soil in the transformer shop area. The total potential risk of 2×10^{-3} is driven by PCBs; all COPCs with potential carcinogenic risk greater than 10^{-6} are identified as COCs, as presented in Section 8.2.3.

Target endpoint HIs are below 1 for all Landside receptors under the RME scenario with the following exceptions:

- RME construction worker – inhalation of vanadium as particulates from soil (surface and subsurface) in the warehouse and laydown area; HI of 3 based on respiratory effects.
- RME construction worker – ingestion and dermal contact with PCBs in soil (surface and subsurface) in the transformer shop area; HI of 1.6 based on eye, nail, and immune effects.
- RME outdoor industrial worker – ingestion and dermal contact with PCBs in surface soil in the transformer shop area; HI of 124 based on eye, nail, and immune effects.
- RME future indoor industrial worker – inhalation of tetrachloroethylene, trichloroethylene, and vinyl chloride along the southern property boundary.

8.1.4.2 Waterside Scenarios

The cumulative RME and CTE cancer risks and noncancer hazards for the waterside receptors are summarized in the following table.

Waterside Receptors – Cumulative Risks/Hazards				
Exposure Area	Cancer		Noncancer [a]	
	RME	CTE	RME	CTE
Swimmer Adult/Young Child [a]				
Waterside Investigation Area (Direct Contact) [b]	2E-06	9E-08	0.08	0.008
Wader Adult/Young Child [a]				
Waterside Investigation Area (Direct Contact) [b]	4E-06	2E-07	0.2	0.02
Shoreline Worker				
Waterside Investigation Area (Direct Contact) [b]	4E-06	1E-07	0.09	0.008
Recreational Angler Adult/Young Child [a,c]				
Anacostia River [c] (Fish Consumption and Direct Contact)				
Upper Anacostia (Total PCBs)	4E-05	2E-06	3	0.3
Upper Anacostia (PCB-TEQ)	2E-05	1E-06	0.7	0.06

Notes:
Blue highlighting indicates that risk exceeds 10^{-6} but is less than or equal to 10^{-4}.
Yellow highlighting indicates that risk exceeds 10^{-4} or the target endpoint HI exceeds 1. The highest target endpoint HI is shown.
[a] Cancer risks for the swimmer, wader, and angler represent the combined adult and child, and noncancer hazards represent the child only. See Section 6 tables for age-specific risks/hazards.
[b] Includes incidental ingestion and dermal contact with fringe surface sediment and surface water.
[c] Includes incidental ingestion and dermal contact with fringe surface sediment and surface water, and consumption of a mixed fish diet. The Upper Anacostia encompasses the Waterside Investigation Area (see **Figure 3-7**).

Potential cancer risks in the Waterside Investigation Area do not exceed 10^{-4}. The HI exceeds 1 only for the recreational fish consumption pathway. The potential cumulative carcinogenic risk for the RME adult/child recreational angler who is assumed to contact fringe surface sediment and surface water within the Waterside Investigation Area and eat fish caught adjacent to the Site every year for 26 years is 4×10^{-5} (based on total PCBs). Under the CTE scenario, the potential cumulative risk for the adult/child recreational angler is equal to 2×10^{-6}. The highest target endpoint HI for the RME young child recreational angler is 3 and is driven by PCBs in fish tissue (based on total PCBs for eye, nail, and immune effects). Using CTE assumptions, the noncancer HIs for all age groups are below 1. All COPCs with potential carcinogenic risk greater than 10^{-6} or HI greater than 1 are identified as COCs, as presented in Section 8.2.3.

8.1.4.3 Background and Regional River Reaches

The fish consumption RME and CTE cancer risks and noncancer hazards are summarized in the following table.

Regional and Background Reaches– Fish Consumption Risks/Hazards				
Exposure Area	**Cancer [a]**		**Noncancer [a]**	
	RME	**CTE**	**RME**	**CTE**
Recreational Angler Adult/Young Child				
Background Area [b] (Fish Consumption)				
Upstream Non-Tidal Anacostia (Total PCBs)	7E-06	5E-07	0.6	0.1
Upstream Non-Tidal Anacostia (PCB-TEQ)	8E-06	5E-07	0.6	0.1
Regional Reaches [b] (Fish Consumption)				
Lower Anacostia (Total PCBs)	7E-05	3E-06	5	0.5
Lower Anacostia (PCB-TEQ)	9E-05	4E-06	3	0.3
Lower Potomac (Total PCBs)	6E-05	2E-06	2	0.3
Lower Potomac (PCB-TEQ)	6E-05	2E-06	1	0.1
Upper Potomac (Total PCBs)	2E-04	5E-06	10	0.7
Upper Potomac (PCB-TEQ)	2E-04	7E-06	9	0.5

Notes:
Blue highlighting indicates that risk exceeds 10^{-6} but is less than or equal to 10^{-4}.
Yellow highlighting indicates that risk exceeds 10^{-4} or the target endpoint HI exceeds 1. The highest target endpoint HI is shown.
[a] Cancer risks represent the combined adult and child, and noncancer hazards represent the child only. See Section 6 tables for age-specific risks/hazards.
[b] Includes consumption of a mixed fish diet only.
[c] CTE scenario was not included for the high-end consuming angler scenario.

The potential cumulative carcinogenic risks for the RME adult/child recreational angler who eats fish from river reaches other than the Upper Anacostia (Waterside Investigation Area) are 2×10^{-4} for the Upper Potomac, 6×10^{-5} for the Lower Potomac, and 7×10^{-6} for the Upstream Non-Tidal Anacostia background (based on total PCBs). In the Lower Anacostia River, potential cumulative carcinogenic risk for the RME adult/child recreational angler is 7×10^{-5} (based on total PCBs). In all of these fish consumption scenarios, potential risks are driven mainly by PCBs, with 4,4-DDE, dieldrin, heptachlor epoxide, and arsenic contributing to a lesser extent in select areas.

The total potential HI for the RME recreational angler in the background and regional reaches exceeds the target noncancer HI of 1 except for the Upstream Non-Tidal Anacostia background reach. The exceedance of the noncancer target HI of 1 is due to PCBs in fish tissue (based on both total PCBs for eye, nail, and immune effects and PCB-TEQ for reproductive and developmental effects). For the young child age group, which has the highest noncancer hazards, RME HIs for the background and regional reaches range from 0.6 (Upstream Non-Tidal Anacostia) to 10 (Upper Potomac, total PCBs). Using CTE assumptions, the noncancer HIs for all age groups and areas are below 1.

As discussed in Section 7.3.2, potential risks and hazards for the recreational receptor are dependent on the species consumed. For example, based on consumption of a diet including catfish only (which is a preferred species based on local angler surveys), the HI for the young child in the Upper Anacostia decreases by almost 30%, and based on consumption of largemouth bass only, decreases to an acceptable HI of 1.

As noted in 7.3.2.2, potential risks and hazards for the high-end consuming angler exceed a cancer risk level of 10^{-4} in all but the Upstream Non-Tidal Anacostia River reach, where the cancer risk is within USEPA's risk range. The HI exceeds 1 for all reaches. As for the recreational angler, the highest potential total PCB risks for the high-end consuming angler are in the Upper Potomac.

8.2 Conclusions

The conclusions of the BHHRA for the Study Area are described in this section.

8.2.1 Landside Investigation Area

Potential exposures to on-Site surface and subsurface soils are currently incomplete due to perimeter fencing, round-the-clock Site security, and the presence of pavement or gravel across the vast majority of the Site. The current lack of access to soil is expected to continue into the foreseeable future. However, the potential for future direct contact exposures to surface and subsurface soil was evaluated. It was also assumed that a construction worker may be potentially exposed via inhalation of vapors from groundwater in an excavation trench. The total potential carcinogenic risk and noncarcinogenic hazards for all Landside receptor scenarios are within or below the USEPA target risk range of 10^{-4} to 10^{-6} and below a target endpoint-specific HI of 1 with the exception of the following:

- RME construction worker in the warehouse and laydown area due to vanadium in soil
- RME construction worker in the transformer shop due to total PCBs in soil
- RME future outdoor industrial worker in the transformer shop due to total PCBs in soil
- RME future indoor industrial worker due to chloroform along the northern boundary and tetrachloroethylene, trichloroethylene, and vinyl chloride in groundwater along the southern property boundary

The Landside receptor scenarios with risks above or within the risk range of 10^{-6} to 10^{-4} or with HIs above 1 were described above in Section 8.1.4.1, and include direct contact with soil (2,3,7,8-TCDD-TEQ, vanadium, total PCBs) and inhalation of VOCs in indoor air (future building scenario only)

Migration of chemicals in Site groundwater to the Anacostia River was also evaluated. In-stream concentrations of chemicals detected in groundwater at the downgradient edge of the property were modeled using conservative dilution attenuation factors. No modeled in-stream concentrations exceeded state and federal surface water screening levels, which indicates that Site groundwater is not adversely impacting the Anacostia River.

8.2.2 Waterside Investigation Area

- None of the potential cumulative receptor carcinogenic risks for the recreational angler exceed the upper end of USEPA's target risk range of 10^{-6} to 10^{-4} for the Waterside Investigation Area for the RME scenario. Recreational angler risks within the risk range of 10^{-6} to 10^{-4} were described above in Section 8.1.4.2. Noncarcinogenic hazards for the recreational angler exceed USEPA's target of an HI of 1 for consumption of Upper Anacostia River fish, as well as consumption of fish from the Upper Potomac River and Lower Potomac and Lower Anacostia Rivers for the RME scenario. The HI is less than 1 for the Upstream Non-Tidal Anacostia River (background area). The HI for fish consumption is less than 1 for all receptors in all areas under the CTE scenario.
- Potential human health risks to recreational receptors and workers posed by direct contact with fringe surface sediment and surface water in the Waterside Investigation Area are within or below USEPA's target risk levels. Potential risks within the risk range of 10^{-6} to 10^{-4} were described above in Section 8.1.4.2 and direct contact with fringe surface sediment (2,3,7,8-TCDD-TEQ).
- PCBs in fish tissue are the dominant COPC and medium driving potential risk; other COPCs contribute much less to cumulative risk*.* PCBs in fish tissue were evaluated separately as total PCBs and as PCB-TEQ. There was little difference between estimated fish consumption cancer risks based on total PCBs and PCB-TEQ. The potential noncancer hazards based on PCB-TEQ were generally lower than corresponding noncancer hazards based on total PCBs.
- Fish consumption hazards estimated using data collected from sampling locations throughout the tidal Anacostia and Potomac Rivers exceed the noncancer target HI of 1; these findings suggest multiple sources of PCBs in the River.

As noted in Section 7.1.2, the COPC concentrations detected in the fish tissue composite samples likely represent conditions throughout the approximately 3.2-mile Upper Anacostia River sampling area and may not be representative of conditions in the Waterside Investigation Area.

8.2.3 Potential COCs

COPCs with a potential risk above 1 x 10^{-6} are summarized in the tables below.

Potential COC	Risk/HI	Landside Investigation Area - Soil			
		Warehouse and Laydown Area	Salvage Yard and Storage Area	Substation #7	Transformer Shop
2,3,7,8-TCDD-TEQ	Risk	--	4E-06[a]	--	--
Vanadium	HI	3[b]	--	--	--
Total PCBs	Risk	5E-06[a]	2E-06[a]	4E-6[a]	2E-03[a]
	HI	--	--	--	124[a] 1.6[b]

Notes:
-- Indicates that risk is less than or equal to 10^{-6} or HI is less than or equal to 1.
Blue highlighting indicates that risk exceeds 10^{-6} but is less than or equal to 10^{-4}.
Yellow highlighting indicates that risk exceeds 10^{-4} or the target endpoint HI exceeds 1.
[a] Future outdoor industrial worker surface soil (0-1 foot bgs).
[b] Current/future construction worker soil (0-16 feet bgs).

COPC	Risk/HI	Landside Investigation Area - Future Vapor Intrusion Pathway[a]	
		Southern Boundary	Northern Boundary (DP-60)
Chloroform	Risk	--	4E-06
Tetrachloroethylene	Risk	7E-06	--
	HI	2	--
Trichloroethylene	Risk	6E-06	--
	HI	2	--
Vinyl Chloride	Risk	2E-06	--

Notes:
-- Indicates that risk is less than or equal to 10^{-6} or HI is less than or equal to 1.
Blue highlighting indicates that risk exceeds 10^{-6} but is less than or equal to 10^{-4}.
Yellow highlighting indicates that risk exceeds 10^{-4} or the target endpoint HI exceeds 1.
[a] Future indoor industrial worker, assuming buildings are constructed in these areas.

Potential COC	Risk/HI	Fish Tissue [a]	Fringe Surface Sediment
		Upper Anacostia	Pepco Waterside Investigation Area
2,3,7,8-TCDD-TEQ	Risk	--	2E-06 [a] 3E-06 [b,c]
Total PCBs	Risk	3E-05	--
	HI	3	--
PCB-TEQ	Risk	1E-05	--
Dieldrin	Risk	5E-06	--

Notes:
-- Indicates that risk is less than or equal to 10^{-6} or HI is less than or equal to 1.
Blue highlighting indicates that risk exceeds 10^{-6} but is less than or equal to 10^{-4}.
Yellow highlighting indicates that risk exceeds 10^{-4} or the target endpoint HI exceeds 1.
[a] Current/future recreational angler.
[b] Current/future shoreline worker.
[c] Current/future wader.

Potential fish consumption risks and hazards were also calculated for the background and other regional river reaches to provide important context for the Upper Anacostia area. For comparative purposes, the table below presents the chemicals with potential risks greater than 10^{-6} or a target endpoint HI of 1; the hazard value representing the highest target endpoint HI is presented. All of the chemicals identified as potential COCs in the Upper Anacostia area for fish consumption are also identified in the regional river reaches, and in many cases, at higher risk and hazard levels. These results are indicative of a regional impact on fish tissue body burdens that may be attributable, at least in part, to sources other than sediment within the Upper Anacostia River reach or the Waterside Investigation Area in particular.

Chemical	Risk/ HI	Fish Tissue [a]			
		Regional Reaches			Background Area
		Lower Anacostia	Lower Potomac	Upper Potomac	Non-tidal Anacostia
Arsenic	Risk	2E-06	3E-05	3E-06	--
Total PCBs	Risk	5E-05	2E-05	1E-04	3E-06
	HI	5	2	14	--
PCB-TEQ	Risk	7E-05	3E-05	2E-04	4E-06
	HI	3	--	9	--
4,4-DDE	Risk	--	--	4E-06	
Dieldrin	Risk	1E-05	5.0E-06	2E-05	
Heptachlor epoxide	Risk	2E-06	--	--	

Notes:
-- Indicates that risk is less than or equal to 10^{-6} or HI is less than or equal to 1.
Blue highlighting indicates that cumulative risk exceeds 10^{-6} but is less than or equal to 10^{-4}.
Yellow Highlighting indicates that cumulative risk exceeds 10^{-4} or the target endpoint HI exceeds 1.
[a] Current/future recreational angler.

As with all risk assessments, assumptions have been made about variables and processes that are not fully known, such as human behavior, chemical toxicity, or environmental concentrations. While the use of assumptions leads to uncertainty, it is important to note that the assumptions and approaches used in this BHHRA are conservative, such that risks are much more likely to be overestimated than underestimated. In addition, information regarding risks associated with conditions in background and other regional areas should be carefully considered in risk management decision-making for the Study Area.

Notes:

FD = Field duplicate.
N = Normal sample
Soil samples collected at depths greater than 16 feet bgs were not included in the BHHRA data set.
(a) Sample collected beneath an obstruction (e.g., concrete or pavement). Sample depth measured from top of slab. Sample was collected immediately below slab and is therefore considered surface soil for potential future exposures.

Exposure Areas:

Maintenance: Stores and Fleet Maintenance Area
Offices/Parking: Offices and Parking Lot
Future Park/Green Hypothetical Future Park Land/Green Space
Salvage: Salvage Yard and Waste Storage Area
Substation #7: Substation #7
Transformer Shop: Transformer Shop
Vehicle Refueling: Vehicle Refueling Area
Warehouse: Warehouse and Laydown Area

Notes:
FD = Field duplicate.
N = Normal sample
(a) Data from lower aquifer used only in the evaluation of groundwater migration to surface water. Data collected in 2016 were used where available. Otherwise, data collected in 2014 was used.such that for each chemical and well combination, the most recent data point was used.

Exposure Areas:

Maintenance: Stores and Fleet Maintenance Area
Offices/Parking: Offices and Parking Lot
Future Park/Green Hypothetical Future Park Land/Green Space
Salvage: Salvage Yard and Waste Storage Area
Substation #7: Substation #7
Transformer Shop: Transformer Shop
Vehicle Refueling: Vehicle Refueling Area
Warehouse: Warehouse and Laydown Area

Notes:
DOEE = Department of Energy and Environment
N = Normal sample
FD = Field duplicate
Sources:
Pepco collected Site-specific background sediment samples during the Phase I and Phase II field investigations.
Sediment samples were collected by Tetra Tech on behalf of DOEE to support Phase I and Phase II of the Anacostia River Sediment Project.

Notes:
FD = Field Duplicate
M = Metals
N = Normal sample
O = Organics

(a) - The samples collected in the Upper Anacostia River are assumed to reflect overall conditions within the several mile long river reach that was sampled (or the possibly larger home range for some of the fish species sampled), and may not reflect the specific conditions within the Waterside Investigation Area.
(b) - Duplicate of P2-NWB-002-GT1A.

Table 3-9
Sediment and Soil Screening Levels
Benning Road Facility RI/FS Project
3400 Benning Rd, N.E., Washington DC 20019

CAS Number	Chemical	Sediment Residential RSL (a) (mg/kg)	Soil Industrial RSL (a) mg/kg

Notes:
CAS - Chemical Abstracts Service.
EN - Essential Nutrient.
NA - Not Available; no appropriate surrogate.
RSL - Regional Screening Level.
USEPA - United States Environmental Protection Agency.

(a) USEPA Regional Screening Level Table. (Target Risk =1E-06; Target Hazard Quotient=0.1). November 2018.
https://www.epa.gov/risk/regional-screening-levels-rsls
Residential value used for sediment, industrial value used for soil.
(b) - Value for 2,3,7,8-Tetrachlorodibenzo-p-dioxin (2,3,7,8-TCDD).
(c) - Value for acenaphthene
(d) - Value for pyrene.
(e) - Value for fluorene.
(f) - Value for chlordane.
(g) - Value for alpha-BHC.
(h) - Value for total petroleum hydrocarbons (aliphatic medium). THQ of 1 used to account for uncertainty in toxicity data.
(i) - Value for diethylphthalate.
(j) - Value for endosulfan.
(k) - Value for endrin.
(l) - Value for total petroleum hydrocarbons (aromatic low).
(m) - Value for m-xylenes.
(n) - Value for manganese, non-diet.
(o) - Value for mercuric chloride.
(p) - Value for cyclohexane.
(q) - Value for total petroleum hydrocarbons (aliphatic high).
(r) - Value for Aroclor-1254.
(s) - Value for anthracene.

Table 3-11
Surface Water Screening Levels
Benning Road Facility RI/FS Project
3400 Benning Rd, N.E., Washington DC 20019

CAS Number	Chemical	DOEE Class D Surface Water Criteria (a) (ug/L)	NRWQC, Human Health, Organism only (b) (ug/L)	Tapwater RSL (c) (ug/L)	Selected (d) (ug/L)

Notes:
CAS - Chemical Abstracts Service.
DOEE - District Department of Energy and Environment.
EN - Essential Nutrient.
NA - Not Available from this source.
NRWQC - National Recommended Water Quality Criteria.
RSL - Regional Screening Level.
USEPA - United States Environmental Protection Agency.

(a) - DOEE, Title 21 of the District of Columbia Municipal Regulations, Chapter 11, Water Quality Standards. Rule 21-1104, Standards. Effective 11/1/2013.
https://www.dcregs.dc.gov/Common/DCMR/SectionList.aspx?SectionNumber=21-1104
(b) - USEPA, National Recommended Water Quality Criteria for Priority Pollutants. Value for Human Health for the consumption of organisms. Accessed 8/2018.
https://www.epa.gov/wqc/national-recommended-water-quality-criteria-human-health-criteria-table.
(c) USEPA Regional Screening Level Table. (Target Risk =1E-06; Target Hazard Quotient=0.1). November 2018. Value for tapwater.
https://www.epa.gov/risk/regional-screening-levels-rsls
(d) Selected screening level is the lower of the DOEE criteria, where available. If a DOEE criteria is not available, the NRWQC is used.
Where neither is available, the tapwater RSL is selected.
(e) Value for trans-1,2-Dichloroethene.
(f) - Value for 1,3-dichloropropene.
(g) - Value for 1,4-dichlororobenzene.
(h) - Value for phenol.
(i) - Value for 4-nitroaniline.
(j) - Value for acenaphthene
(k) - Value for pyrene.
(l) - Value for chlordane.
(m) - Value for alpha-BHC.
(n) - Value for total petroleum hydrocarbons (aliphatic medium). THQ of 1 used to account for uncertainty in toxicity data.
(o) Value for diethylphthalate.
(p) - Value for endosulfan.
(q) - Value for endrin.
(r) - Value for total petroleum hydrocarbons (aromatic low).
(s) - Value for m-xylenes.
(t) - Value for mercuric chloride.
(u) - Value for cyclohexane.
(v) - Value for total petroleum hydrocarbons (aliphatic high).
(w) - Value for polychlorinated biphenyls, low risk.
(x) - Value for anthracene.
(y) - Value for benzo(a)pyrene.
(z) - Value for 2,3,7,8-Tetrachlorodibenzo-p-dioxin (2,3,7,8-TCDD).
(aa) - Value for fluorene.
(ab) - Value for isopropanol.
(ac) - Value for methyl tert-Butyl Ether (MTBE).

PCB-TEQ	PCB-TEQ	3.20E-08	c	2,3,7,8-tetrachlorodibenzo(p)dioxin

Notes:
c - Value is based on carcinogenic effects.
CAS - Chemical Abstracts Service.
EN - Essential nutrient.
mg/kg - milligram per kilogram.
nc - Value is based on noncarcinogenic effects.
NSL - No Screening Level.
PBDE - Polybrominated Diphenyl Ether.
PCB - Polychlorinated Biphenyl.
RSL - Regional Screening Level.
(a) Fish tissue screening levels are equal to the USEPA Regional Screening Levels (RSLs) for fish tissue, calculated using USEPA's RSL calculator based on a fish ingestion rate of 54 g/day, a target risk level of 1x10-6 for carcinogens and a target hazard quotient of 0.1 for noncarcinogens. Accessed on July 2018.
(b) Hexavalent chromium was not identified as a constituent of concern associated with sites along the Anacostia River Therefore chromium was evaluated as trivalent chromium. See Table 3.2 in Remedial Investigation Work Plan: Anacostia River Sediment Project, Washington D.C., prepared for the Department of Energy and the Environment. June 2014.
(c) Letter from Superfund Technical Support Center to Marian Olsen dated February 25, 2015. Approval of Surrogates for Multiple Chemicals. 2,4'-DDT, 2,4'-DDD and 2,4'-DDE.
(d) Letter from Superfund Technical Support Center to Marian Olsen dated April 9, 2015. Approval of Surrogates for Multiple Chemicals. Cis- and trans-nonachlor and oxychlordane.

Notes:

(1) Minimum/maximum detected concentration and associated data flags.
J = The chemical was positively identified; however, the associated numerical value is an estimated concentration.
+/- = Indicates the result may be biased high/low.
(2) Lab Reporting Detection Limits (RDLs) are shown where the frequency of detection is less than 100%.
(3) Maximum detected concentration used for screening, except for lead for which the mean detected concentration is used.
(4) Screening levels are equal to the USEPA Regional Screening Level (RSL) for industrial soil based on a target risk level of 1x10-6 for carcinogens and a target hazard quotient of 0.1 for noncarcinogens (November 2018)
See Table 3-9 for screening levels and surrogates used.
Although iron has a USEPA RSL for soil, iron is considered an essential nutrient and is not further evaluated.
The average concentration of lead is used for comparison to the screening level, consistent with USEPA guidance.
(5) Rationale Codes:
Selection Reason: Above Screening Level (ASL)
Deletion Reason: Below Screening Level (BSL); Essential Nutrient (EN)
(6) Soil data represent the 0 to 16 feet depth interval.
(7) All seven potentially carcinogenic PAH compounds were retained as COPCs if one or more was identified as a COPC.

Definitions:

PCB - Polychlorinated Biphenyl
SVOC - Semivolatile Organic Compound
TCDD-TEQ - Dioxin Toxic Equivalence
VOC - Volatile Organic Compound
CAS - Chemical Abstracts Service
cPAH - Carcinogenic Polycyclic Aromatic Hydrocarbon
mg/kg - milligrams per kilogram

Notes:

(1) Minimum/maximum detected concentration and associated data flags.
J = The chemical was positively identified; however, the associated numerical value is an estimated concentration.
+/- = Indicates the result may be biased high/low.

(2) Lab Reporting Detection Limits (RDLs) are shown where the frequency of detection is less than 100%.

(3) Maximum detected concentration used for screening.

(4) Screening levels are equal to the USEPA Regional Screening Level (RSL) for tapwater based on a target risk level of $1x10^{6}$ for carcinogens and a target hazard quotient of 0.1 for noncarcinogens (November 2018).
See Table 3-10 for screening levels and surrogates used.

(5) Rationale Codes:
Selection Reason: Above Screening Level (ASL)
Deletion Reason: Below Screening Level (BSL), No Inhalation Toxicity Data (NIT)

Definitions:

CAS - Chemical Abstracts Service
COPC - Chemical of Potential Concern
PCB TEQ - Polychlorinated Biphenyl Toxicity Equivalence
TCDD TEQ - Dioxin Toxic Equivalence

Table 3-15
Occurrence, Distribution and Selection of Chemicals of Potential Concern in Fringe Surface Sediment
Benning Road Facility RI/FS Project
3400 Benning Rd, N.E., Washington DC 20019

Scenario Timeframe: Current/Future

	1336-36-3	Total PCBs	2.20E-02	1.90E+00	4.47E-01	mg/kg	SED7.5E (0 - 0.5 ft)	41 / 41	-	1.90E+00	1.20E-01	**Y**	**ASL**

Notes:

(1) Minimum/maximum detected concentration and associated data flags.
J = The chemical was positively identified; however, the associated numerical value is an estimated concentration.
+/- = Indicates the result may be biased high/low.
(2) Lab Reporting Detection Limits (RDLs) are shown where the frequency of detection is less than 100%.
(3) Maximum detected concentration used for screening, except for lead for which the mean detected concentration is used.
(4) Sediment screening levels are equal to the USEPA Regional Screening Levels (RSLs) for residential soil based on a target risk level of 1x10^{-6} for carcinogens and a target hazard quotient of 0.1 for noncarcinogens (November 2018). See Table 3-9 for screening levels and surrogates used. Although iron has a USEPA RSL for soil, iron is considered an essential nutrient and is not further evaluated.
(5) Rationale Codes:
Selection Reason: Above Screening Level (ASL)
Deletion Reason: Below Screening Level (BSL); Essential Nutrient (EN)
(6) Sediment data represent fringe sediment from the 0 to 0.5 foot below ground surface depth interval.
(7) All seven potentially carcinogenic PAH compounds were retained as COPCs if one or more was identified as a COPC.

Definitions:

CAS - Chemical Abstracts Service
COPC - Chemical of Potential Concern
cPAH - Carcinogenic Polycyclic Aromatic Hydrocarbon
EN - Essential Nutrient
ft - Feet
mg/kg - milligrams per kilogram
PAH - Polycyclic Aromatic Hydrocarbon
PCB - Polychlorinated Biphenyl
SVOC - Semivolatile Organic Compound
TCDD-TEQ - Dioxin Toxic Equivalence
TPH - Total Petroleum Hydrocarbon
VOC - Volatile Organic Compound

Notes:

(1) Minimum/maximum detected concentration and associated data flags.
J = The chemical was positively identified; however, the associated numerical value is an estimated concentration only.
(2) Lab Reporting Detection Limits (RDLs) are shown where the frequency of detection is less than 100%.
(3) Maximum detected concentration used for screening.
(4) Surface water screening levels were selected based on the following hierarchy:
1. District Department of the Environment. Title 21 of the District of Columbia Municipal Regulations, Chapter 11, Water Quality Standards. Effective November 1, 2013.
2. USEPA National Recommended Water Quality Criteria for Priority Pollutants. Value for Human Health for the consumption of organisms. 2009.
3. USEPA Regional Screening Level (RSL) for Tapwater based on a target risk level of $1x10^{-6}$ for carcinogens and target hazard quotient of 0.1 for noncarcinogens (November 2018).
See Table 3-11 for surface water screening levels and surrogates used.
(5) Rationale Codes:
Selection Reason: Above Screening Level (ASL)
Deletion Reason: Below Screening Level (BSL); Essential Nutrient (EN)
(6) PCBs was not detected in surface water via Method 8082; the lowest reporting limit of 0.0094 ug/L was used for screening.

Definitions:

CAS - Chemical Abstracts Service
COPC - Chemical of Potential Concern
EN - Essential Nutrient.
ug/L - microgram per liter
NA - Not Available
PCB - Polychlorinated biphenyl
SVOC - Semivolatile organic compound
TCDD-TEQ - Dioxin Toxic Equivalence
VOC - Volatile organic compound

Table 3-17
Occurrence, Distribution and Selection of Chemicals of Potential Concern in Fish Tissue - Upper Anacostia River
Benning Road Facility RI/FS Project
3400 Benning Rd, N.E., Washington DC 20019

Scenario Timeframe: Current/Future
Medium: Fish Tissue
Exposure Medium: Fish Tissue (fillet)

Exposure Point	CAS Number	Chemical	Minimum Detected Concentration [1]	Maximum Detected Concentration [1]	Average Detected Concentration [2]	Units	Species with Maximum Concentration	Detection Frequency	Range of Reporting Limits [7]	Concentration Used for Screening [3]	Screening Toxicity Value [4]	COPC Flag (Y/N)	Rationale for Selection or Deletion [5]
Upper Anacostia[8]	**Polychlorinated Biphenyls**												
	1336-36-3	Total PCBs (Congeners)	4.16E-02	6.81E-01	1.92E-01	mg/kg	Carp	7 / 7	--	6.81E-01	2.08E-03	Y	ASL
	PCB-TEQ	PCB-TEQ	1.17E-07	5.33E-06	1.30E-06	mg/kg	Largemouth bass	7 / 7	--	5.33E-06	3.20E-08	Y	ASL

Notes:

(1) Minimum/maximum detected concentration and associated data flags.
J = The chemical was positively identified; however, the associated numerical value is an estimated concentration.
+/- = Indicates the result may be biased high/low.
(2) Average of detected results.
(3) Maximum detected concentration used for screening.
(4) Fish tissue screening levels are equal to the USEPA Regional Screening Levels (RSLs) for fish tissue, calculated using USEPA's RSL calculator based on a target risk level of $1x10^{-6}$ for carcinogens and a target hazard quotient of 0.1 for noncarcinogens. Accessed July 2018. See Table 3-12 for screening levels and surrogates used.
(5) Rationale Codes:
Selection Reason: Above Screening Level (ASL)
Deletion Reason: Below Screening Level (BSL); Essential Nutrient (EN); No Screening Level (NSL)
(6) All chlordane isomer compounds were retained as COPCs if one or more was identified as a COPC.
(7) Range of detection limits for constituents with nondetects. Presented with minimum followed by maximum nondetect concentration.
(8) The samples collected in the Upper Anacostia River are assumed to reflect overall conditions within the several mile long river reach that was sampled (or the possibly larger home range for some of the fish species sampled), and may not reflect the specific conditions within the Waterside Investigation Area.

Definitions:

CAS - Chemical Abstracts Service
COPC - Chemical of Potential Concern
EN - Essential Nutrient
mg/kg - milligrams per kilogram
NSL - No Screening Level
PBDE - Polybrominated diphenyl ethers
PCB - Polychlorinated Biphenyl
TEQ - Toxicity Equivalence

Notes:
(1) Minimum/maximum detected concentration and associated data flags.
J = The chemical was positively identified; however, the associated numerical value is an estimated concentration.
+/- = Indicates the result may be biased high/low.
(2) Average of detected results.
(3) Maximum detected concentration used for screening.
(4) Fish tissue screening levels are equal to the USEPA Regional Screening Levels (RSLs) for fish tissue, calculated using USEPA's RSL calculator based on a target risk level of $1x10^{-6}$ for carcinogens and a target hazard quotient of 0.1 for noncarcinogens. Accessed July 2018. See Table 3-12 for screening levels and surrogates used.
(5) Rationale Codes:
Selection Reason: Above Screening Level (ASL)
Deletion Reason: Below Screening Level (BSL); Essential Nutrient (EN); No Screening Level (NSL)
(6) Range of detection limits for constituents with nondetects. Presented with minimum followed by maximum nondetect concentration.

Definitions:
CAS - Chemical Abstracts Service
COPC - Chemical of Potential Concern
EN - Essential Nutrient
mg/kg - milligrams per kilogram
NSL - No Screening Level
PBDE - Polybrominated diphenyl ethers
PCB - Polychlorinated Biphenyl
TEQ - Toxicity Equivalence

Table 3-19
Occurrence, Distribution and Selection of Chemicals of Potential Concern in Fish Tissue - Upper Potomac River
Benning Road Facility RI/FS Project
3400 Benning Rd, N.E., Washington DC 20019

Scenario Timeframe: Current/Future
Medium: Fish Tissue
Exposure Medium: Fish Tissue (fillet)

Exposure Point	CAS Number	Chemical	Minimum Detected Concentration [1]	Maximum Detected Concentration [1]	Average Detected Concentration [2]	Units	Species with Maximum Concentration	Detection Frequency	Range of Reporting Limits [7]	Concentration Used for Screening [3]	Screening Toxicity Value [4]	COPC Flag (Y/N)	Rationale for Selection or Deletion [5]

Notes:

(1) Minimum/maximum detected concentration and associated data flags.
J = The chemical was positively identified; however, the associated numerical value is an estimated concentration.
+/- = Indicates the result may be biased high/low.

(2) Average of detected results.

(3) Maximum detected concentration used for screening.

(4) Fish tissue screening levels are equal to the USEPA Regional Screening Levels (RSLs) for fish tissue, calculated using USEPA's RSL calculator based on a target risk level of $1x10^{-6}$ for carcinogens and a target hazard quotient of 0.1 for noncarcinogens. Accessed July 2018. See Table 3-12 for screening levels and surrogates used.

(5) Rationale Codes:
Selection Reason: Above Screening Level (ASL)
Deletion Reason: Below Screening Level (BSL); Essential Nutrient (EN); No Screening Level (NSL)

(6) All chlordane isomer compounds were retained as COPCs if one or more was identified as a COPC.

(7) Range of detection limits for constituents with nondetects. Presented with minimum followed by maximum nondetect concentration.

Definitions:

CAS - Chemical Abstracts Service
COPC - Chemical of Potential Concern
EN - Essential Nutrient
mg/kg - milligrams per kilogram
NSL - No Screening Level
PBDE - Polybrominated diphenyl ethers
PCB - Polychlorinated Biphenyl
TEQ - Toxicity Equivalence

Table 3-20
Occurrence, Distribution and Selection of Chemicals of Potential Concern in Fish Tissue - Lower Potomac River
Benning Road Facility RI/FS Project
3400 Benning Rd, N.E., Washington DC 20019

Scenario Timeframe: Current/Future
Medium: Fish Tissue
Exposure Medium: Fish Tissue (fillet)

Exposure Point	CAS Number	Chemical	Minimum Detected Concentration [1]	Maximum Detected Concentration [1]	Average Detected Concentration [2]	Units	Species with Maximum Concentration	Detection Frequency	Range of Reporting Limits [7]	Concentration Used for Screening [3]	Screening Toxicity Value [4]	COPC Flag (Y/N)	Rationale for Selection or Deletion [5]

Notes:

(1) Minimum/maximum detected concentration and associated data flags.
J = The chemical was positively identified; however, the associated numerical value is an estimated concentration.
+/- = Indicates the result may be biased high/low.
(2) Average of detected results.
(3) Maximum detected concentration used for screening.
(4) Fish tissue screening levels are equal to the USEPA Regional Screening Levels (RSLs) for fish tissue, calculated using USEPA's RSL calculator based on a target risk level of $1x10^{-6}$ for carcinogens and a target hazard quotient of 0.1 for noncarcinogens. Accessed July 2018. See Table 3-12 for screening levels and surrogates used.
(5) Rationale Codes:
Selection Reason: Above Screening Level (ASL)
Deletion Reason: Below Screening Level (BSL); Essential Nutrient (EN); No Screening Level (NSL)
(6) All chlordane isomer compounds were retained as COPCs if one or more was identified as a COPC.
(7) Range of detection limits for constituents with nondetects. Presented with minimum followed by maximum nondetect concentration.

Definitions:

CAS - Chemical Abstracts Service
COPC - Chemical of Potential Concern
EN - Essential Nutrient
mg/kg - milligrams per kilogram
NSL - No Screening Level
PBDE - Polybrominated diphenyl ethers
PCB - Polychlorinated Biphenyl
TEQ - Toxicity Equivalence

Notes:

CAS - Chemical Abstracts Service
PCB - Polychlorinated biphenyl
SVOC - Semivolatile organic compound
TCDD-TEQ - Dioxin Toxic Equivalence.
X - Indicates chemical was identified as a chemical of potential concern in the associated media.

(a) Total PCBs for abiotic media (soil, sediment, surface water) are evaluated as Total PCB Aroclors. PCBs for biotic media (fish tissue) are evaluated as Total PCB (sum of congeners) and PCB-TEQ. (See text Section 3 for further discussion).
(b) PCBs was not detected in the RI surface water samples, however, the detection limit for the analytical method used (approximately 0.01 ug/L for Method 8082) exceeds the applicable surface water screening level of 0.000064 ug/L for PCBs. Therefore, PCBs was conservatively identified as a surface water COPC using the lowest reporting limit that was achieved (0.0094 ug/L).
(c) All seven potentially carcinogenic polycyclic aromatic hydrocarbons were conservatively retained as COPCs if one or more was identified as a COPC.
(d) Represents total chlordane.
(e) The samples collected in the Upper Anacostia River are assumed to reflect overall conditions within the several mile long river reach that was sampled (or the possibly larger home range for some of the fish species sampled), and may not reflect the specific conditions within the Waterside Investigation Area.

Indeno(1,2,3-cd)pyrene	193-39-5	Chronic	NA	--	NA	NA	NA	NA	NA	NA	NA	NA	NA	NA
Naphthalene	91-20-3	Chronic	2.00E-02	--	2.00E-02	Rat	Oral: gavage	Developmental	Decreased terminal body weight	3,000	Low	IRIS	8/2018	Tier 1
TPH														
Diesel Range Organics (C10-C20)	C10C20	Chronic	1.00E-02 (l)	--	1.00E-02	Rat	Oral: gavage	Liver, Kidney, Blood	Liver/kidney weight increases and other changes, serum chemistry changes	10,000	Low	PPRTV screening value (e)	9/2009	Tier 3

Notes:

"--" - No adjustment necessary.
$ABS_{(GI)}$ - Fraction of contaminant absorbed in gastrointestinal tract (dimensionless).
CAS - Chemical Abstracts Service.
CNS - Central Nervous System.
IRIS - Integrated Risk Information System, an online computer database of toxicological information (USEPA, 2018).
mg/kg-day - Milligrams per Kilogram per day.
NA - Not available/Not Applicable.
PCB - Polychlorinated Biphenyls.
PPRTV - Provisional Peer Reviewed Toxicity Value.
RfD - Reference Dose.
SVOCs - Semi-volatile organic compounds.
TCDD - 2,3,7,8-Tetrachlorodibenzo-p-dioxin.
TEQ - Toxicity Equivalence.
TPH - Total Petroleum Hydrocarbon.
TSH - Thyroid Stimulating Hormone.
USEPA - United States Environmental Protection Agency.

(a) USEPA, 2004. Risk Assessment Guidance for Superfund. Volume 1, Part E, Supplemental Guidance for Dermal Risk Assessment. Exhibit 4-1. Where USEPA, 2004 does not recommend adjustments, no value is listed.
(b) Oral RfD multiplied by ABS_{GI}. Where the gastrointestinal absorption is greater than or equal to 50%, Dermal RfD = Oral RfD.
(c) Value for Aroclor 1254 (2E-05 mg/kg-day) or Aroclor 1016 (7E-05 mg/kg-day) may be used to evaluate the noncarcinogenic hazards of total PCBs, and the Aroclor selected depends on the chlorine content of the PCB congeners in the medium of interest. For this HHRA, the RfD for Aroclor 1254 is used.
(d) - Volatile organic compounds are not chemicals of potential concern for oral or dermal pathways, and are therefore not presented here.
(e) No PPRTVs were developed in the PPRTV document. PPRTV document indicates that it is inappropriate to derive provisional chronic or subchronic RfDs but that information is available which, although insufficient to support derivation of a provisional toxicity value, under current guidelines, may be of limited use to risk assessors as a screening value. The use of screening provisional values is highly uncertain but they used in the USEPA Regional Screening Tables (May 2018).
(f) When assessing exposure to manganese for non-dietary pathways, IRIS recommends applying a modifying factor of 3 to the oral RfD of 0.14 mg/kg-day. The USEPA Regional Screening Level User's Guide also indicates that the average dietary manganese content of the US diet (5 mg/day) be subtracted from the critical dose of 10 mg/day when assessing exposure to non-dietary manganese. Therefore, the RfD is (10 mg/day - 5 mg/day)/Modifying Factor (3) = 1.67 mg/day / 70 kg = 0.024 mg/kg-day.
(g) Dermal pathway not applicable; methyl mercury is used to assess the fish ingestion pathway only.
(h) USEPA, 2003. Human Health Toxicity Values in Superfund Risk Assessments. OSWER Directive 9285.7-53. December 5, 2003. IRIS values are considered Tier 1, PPRTVs are considered Tier 2, and other values, including ATSDR, CalEPA, HEAST, and other non-USEPA values are considered Tier 3 values. Selection of Tier 3 values followed the hierarchy put forth in USEPA's Tier 3 Toxicity Value White Paper, OSWER 9285.7-86, May 16, 2013.
(i) The oral RfD for Vanadium is derived from the IRIS oral RfD for Vanadium Pentoxide by factoring out the molecular weight (MW) of the oxide ion. Vanadium Pentoxide (V205) has a molecular weight of 181.88. The two atoms of Vanadium contribute 56% of the MW. Vanadium Pentoxide's oral RfD of 9E-03 mg/kg-day multiplied by 56% gives a Vanadium oral RfD of 5.04E-03 mg/kg-day.
(j) The IRIS reference dose for 2,3,7,8-TCDD is used to evaluate TCDD-TEQ and PCB-TEQ.
(k) Value for technical chlordane is used as a surrogate.
(l) Value for TPH (Aliphatic Medium), based on the PPRTV for Midrange Aliphatic Hydrocarbon Streams. RfD is considered a screening provisional value (USEPA 2009).
(m) As allowed by guidance (USEPA 1989), the UF of 3 used for extrapolation from subchronic to lifetime exposure was removed to derive a subchronic RfD of 5E-5 mg/kg-day for the construction worker scenario (LOAEL of 5E-3 mg/kg-day divided by uncertainty factor of 100).
(m) Minimal Risk Level for Dimethylarsinic acid (DMA) derived in Appendix A of Toxicological Profile for Arsenic (ATSDR, 2007). The value for organic arsenic is used to assess dietary exposure to fish tissue.

Notes:

ATSDR - Agency for Toxic Substances and Disease Registry.
CalEPA - California Environmental Protection Agency. Office of Environmental Health Hazard Assessment (OEHHA) Toxicity Criteria Database. http://oehha.ca.gov/chemicals.
CAS - Chemical Abstracts Service.
IRIS - Integrated Risk Information System, an online computer database of toxicological information (USEPA, 2018).
NA - Not available/Not Applicable.
PCB - Polychlorinated Biphenyls.
PPRTV - Provisional Peer Reviewed Toxicity Value.
RfC - Reference concentration.
RfD - Reference Dose.
SVOCs - Semi-volatile organic compounds.
TCDD - 2,3,7,8-Tetrachlorodibenzo-p-dioxin.
TPH - Total Petroleum Hydrocarbons.
TEQ - Toxicity Equivalence.
USEPA - United States Environmental Protection Agency.
VOCs - Volatile organic compounds.

(a) USEPA, 2003. Human Health Toxicity Values in Superfund Risk Assessments. OSWER Directive 9285.7-53. December 5, 2003. IRIS values are considered Tier 1, PPRTVs are considered Tier 2, and other values, including ATSDR, CalEPA, HEAST, and other non-USEPA values are considered Tier 3 values. Selection of Tier 3 values followed the hierarchy put forth in USEPA's Tier 3 Toxicity Value White Paper, OSWER 9285.7-86, May 16, 2013.
(b) Value for technical chlordane is used as a surrogate.
(c) - Value for isopropanol.
(d) No PPRTVs were developed in the PPRTV document. PPRTV document indicates that it is inappropriate to derive provisional chronic or subchronic RfDs but that information is available which, although insufficient to support derivation of a provisional toxicity value, under current guidelines, may be of limited use to risk assessors as a screening value. The use of screening provisional values is highly uncertain but they used in the USEPA Regional Screening Tables (November 2017).

Table 4-3
Cancer Toxicity Data For COPCs - Oral/Dermal
Benning Road Facility RI/FS Project
3400 Benning Rd, N.E., Washington DC 20019

Chemical of Potential Concern (e)	CAS Number	Oral Cancer Slope Factor $(mg/kg\text{-}day)^{-1}$	Oral Absorption Efficiency for Dermal (a)	Absorbed Dermal Cancer Slope Factor (b) $(mg/kg\text{-}day)^{-1}$	Study Animal	Study Method	Weight of Evidence/ Cancer Guideline Description (c)	Classification System	Oral CSF/WOE Source(s)	Oral CSF/WOE Date	CSF Tier (g)

Notes:

"--" - No adjustment necessary.
$ABS_{(GI)}$ - Fraction of contaminant absorbed in gastrointestinal tract (dimensionless).
ATSDR - Agency for Toxic Substances and Disease Registry.
CalEPA - California Environmental Protection Agency. Toxicity Criteria Database. https://oehha.ca.gov/chemicals
CAS - Chemical Abstracts Service.
COPC - Chemical of Potential Concern.
CSF - Cancer Slope Factor.
IRIS - Integrated Risk Information System, an online computer database of toxicological information (USEPA, 2017).
mg/kg-day - Milligrams per Kilogram per day.
NA - Not available.
NJDEP - New Jersey Department of Environmental Protection.
NTP - National Toxicology Program.
PCB - Polychlorinated Biphenyls.
PPRTV - Provisional Peer Reviewed Toxicity Value.
SQE - State's Qualified Experts.
TCDD - 2,3,7,8-Tetrachlorodibenzo-p-dioxin.
TEQ - Toxicity Equivalence.
TPH - Total Petroleum Hydrocarbons.
USEPA - United States Environmental Protection Agency.
WOE - Weight-of-Evidence.

(a) USEPA, 2004. Risk Assessment Guidance for Superfund. Volume 1, Part E, Supplemental Guidance for Dermal Risk Assessment. Exhibit 4-1. Where USEPA, 2004 does not recommend adjustments, no value is listed.
(b) Oral CSF divided by ABSGI. Where the gastrointestinal absorption is greater than or equal to 50%, Dermal CSF = Oral CSF.
(c) Some chemicals are classified under the 1986 system, while others have been classified under the 2005 system:

1986 Classifications
- Group A: Carcinogenic to Humans.
- Group B: Probably Carcinogenic to Humans:
  - B1: Based on limited human evidence.
  - B2: Based on animal evidence.
- Group C: Possibly Carcinogenic to Humans
- Group D: Not Classifiable as to Human Carcinogenicity.
- Group E: Evidence of Non-carcinogenicity for Humans

2005 Classifications
- Carcinogenic: Carcinogenic to Humans
- Likely Carcinogenic: Likely to be Carcinogenic to Humans
- Suggestive Evidence: Suggestive Evidence of Carcinogenic Potential
- Inadequate: Information Inadequate Information to Assess Carcinogenic Potential
- Not Likely Carcinogenic: Not Likely to be Carcinogenic to Humans

(d) Consistent with the hierarchy used in USEPA's development of Regional Screening Levels (November 2015), the CalEPA cancer slope factor for 2,3,7,8-TCDD is used to evaluate TCDD-TEQ and PCB-TEQ.
(e) - Volatile organic compounds are not chemicals of potential concern for oral or dermal pathways, and are therefore not presented here.
(f) Letter from Superfund Technical Support Center to Marian Olsen, USEPA Region 2, dated April 9, 2015. Approval of Surrogates for Multiple Chemicals. Cis- and trans-nonachlor and oxychlordane.
Value for chlordane is used as a surrogate based on structural similarity, and without the use of relative potency factors, per letters from Superfund Technical Support Center to Marian Olsen, USEPA Region 2, dated August 5, 2015 and November 24, 2015.
(g) USEPA, 2003. Human Health Toxicity Values in Superfund Risk Assessments. OSWER Directive 9285.7-53. December 5, 2003. IRIS values are considered Tier 1, PPRTVs are considered Tier 2, and other values, including ATSDR, CalEPA, PPRTV Appendix Screening Toxicity Values, HEAST and other non-USEPA values are considered Tier 3 values. Selection of Tier 3 values followed the hierarchy put forth in USEPA's Tier 3 Toxicity Value White Paper, OSWER 9285.7-86, May 16, 2013.
(h) Assumed to act via a mutagenic mode of carcinogenic action; therefore, age-dependent adjustment factors are applied to the risk estimates.
(i) Calculated using Relative Potency Factors (RPFs) as per USEPA Guidance for Quantitative Risk Assessment of Polycyclic Aromatic Hydrocarbons (USEPA, 1993).
(j) The cancer assessment for 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) is currently underway (USEPA IRIS, 2018).

ug/m^3 - micrograms per cubic meter.
CalEPA - California Environmental Protection Agency Office of Environmental Health Hazard Assessment (OEHHA).
NTP - National Toxicology Program.
PPRTV - Provisional Peer Reviewed Toxicity Values.
SQE - State's Qualified Experts.
SVOCs - Semi-volatile organic compounds.
USEPA - United States Environmental Protection Agency.

(a) Some chemicals are classified under the 1986 system, while others have been classified under the 2005 system:

1986 Classifications
- Group A: Carcinogenic to Humans.
- Group B: Probably Carcinogenic to Humans:
  - B1: Based on limited human evidence.
  - B2: Based on animal evidence.
- Group C: Possibly Carcinogenic to Humans
- Group D: Not Classifiable as to Human Carcinogenicity.
- Group E: Evidence of Non-carcinogenicity for Humans

2005 Classifications
- Carcinogenic: Carcinogenic to Humans
- Likely Carcinogenic: Likely to be Carcinogenic to Humans
- Suggestive Evidence: Suggestive Evidence of Carcinogenic Potential
- Inadequate: Information Inadequate Information to Assess Carcinogenic Potential
- Not Likely Carcinogenic: Not Likely to be Carcinogenic to Humans

(b) USEPA, 2003. Human Health Toxicity Values in Superfund Risk Assessments. OSWER Directive 9285.7-53. December 5, 2003. IRIS values are considered Tier 1, PPRTVs are considered Tier 2, and other values, including ATSDR, CalEPA, PPRTV Appendix Screening Toxicity Values, HEAST and other non-USEPA values are considered Tier 3 values. Selection of Tier 3 values followed the hierarchy put forth in USEPA's Tier 3 Toxicity Value White Paper, OSWER 9285.7-86, May 16, 2013.
(c) Consistent with the hierarchy used in USEPA's development of Regional Screening Levels (November 2015), the CalEPA cancer slope factor for 2,3,7,8-TCDD is used to evaluate TCDD-TEQ and PCB-TEQ.
(d) Value for chlordane is used as a surrogate based on structural similarity, and without the use of relative potency factors, per letters from Superfund Technical Support Center to Marian Olsen, USEPA Region 2, dated August 5, 2015 and November 24, 2015.
(e) Consistent with the IRIS file for PCBs, for inhalation of dust containing PCBs, the high risk and persistence slope factors are used. The Reasonable Maximum Exposure (RME) unit risk factor presented represents the upper-bound slope factor. The Central Tendency Exposure (CTE) unit risk factor is based on the central-estimate slope factor. The unit risk factors were converted from the slope factors as follows: URF = [CSF (mg/kg-day)-1 x (20 m3/day/70 kg) x 1 mg/1000 ug]
(f) Assumed to act via a mutagenic mode of carcinogenic action. However, no childhood exposue pathways were identified.
(g) Calculated using Relative Potency Factors (RPFs) as per USEPA Guidance for Quantitative Risk Assessment of Polycyclic Aromatic Hydrocarbons (USEPA, 1993).
(h) The cancer assessment for 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) is currently underway (USEPA IRIS, 2018).
(i) Value for continuous exposure during adulthood used; COPC only for the construction worker trench air inhalation pathway.

Table 5-1
Selection of Exposure Pathways
Benning Road Facility RI/FS Project
3400 Benning Rd, N.E., Washington DC 20019

Scenario Timeframe	Medium	Exposure Medium	Exposure Point	Receptor Population	Receptor Age	Exposure Route	Type of Analysis	Rationale for Selection or Exclusion of Exposure Pathway
Current/Future	Biota Tissue	Fish Tissue	Fish from Waterside Investigation Area	Recreational Angler	Young Child (1 to <7 year)	Ingestion	Quantitative	Despite the presence of an advisory warning against the consumption of certain species of fish from the Anacostia and Potomac Rivers, it is assumed that a recreational angler visits the Anacostia River to fish and consumes his/her catch. Assumes receptor will consume fish caught from Anacostia River and share it with family members.
					Older Child/Teen (7 to <19 years)	Ingestion	Quantitative	
					Adult	Ingestion	Quantitative	
		Fish Tissue	Fish from Waterside Investigation Area	High-end Consuming Angler	Young Child (1 to <7 year)	Ingestion	Quantitative	Some anglers may fish on a frequent basis to supplement their diet. While the available survey data indicate there is no evidence of year-round subsistence fishing, a high-end consuming angler who supplements a significant fraction of his/her diet and that of a family with Anacostia River fish is evaluated in the uncertainty analysis.
					Older Child/Teen (7 to <19 years)	Ingestion	Quantitative	
					Adult	Ingestion	Quantitative	
		Shellfish Tissue	Shellfish from Waterside Investigation Area	Angler	Young Child (1 to <7 year)	Ingestion	Qualitative	Anglers and their families may consume shellfish from the Anacostia River; due to limited data on shellfish consumption practices and shellfish tissue chemistry, this pathway is evaluated qualitatively.
					Older Child/Teen (7 to <19 years)	Ingestion	Qualitative	
					Adult	Ingestion	Qualitative	
	Sediment	Fringe Surface Sediment	Waterside Investigation Area	Recreational Angler	Older Child/Teen (7 to <19 years)	Incidental Ingestion	Quantitative	Anglers may contact fringe surface sediment while fishing from the river bank. Assumes that young children under 6 years of age would not typically accompany adult anglers due to safety concerns.
						Dermal Contact	Quantitative	
					Adult	Incidental Ingestion	Quantitative	
						Dermal Contact	Quantitative	
				Swimmer	Young Child (1 to <7 year)	Incidental Ingestion	Quantitative	Swimmers may contact fringe surface sediment while entering and leaving the river and while swimming.
						Dermal Contact	Quantitative	
					Older Child/Teen (7 to <19 years)	Incidental Ingestion	Quantitative	
						Dermal Contact	Quantitative	
					Adult	Incidental Ingestion	Quantitative	
						Dermal Contact	Quantitative	
				Wader	Young Child (1 to <7 year)	Incidental Ingestion	Quantitative	Families visiting the river may contact fringe surface sediment while wading or playing along the shoreline.
						Dermal Contact	Quantitative	
					Older Child/Teen (7 to <19 years)	Incidental Ingestion	Quantitative	
						Dermal Contact	Quantitative	
					Adult	Incidental Ingestion	Quantitative	
						Dermal Contact	Quantitative	
				Worker	Adult	Incidental Ingestion	Quantitative	Workers may be tasked with collecting trash or performing other shoreline maintenance activities with the potential for contact with fringe surface sediment.
						Dermal Contact	Quantitative	

Table 5-1

Notes:

RME = Reasonable Maximum Exposure; CTE = Central Tendency Exposure
-- Chemical-specific value.
(a) On days when the receptor is assumed to have direct contact with Site soil, one-half of the receptor's total daily ingestion exposure to outdoor soil is assumed to come from the Site and the other half while away from the Site (i.e., at home, work, school).

Table 5-4
Values Used for Daily Intake Calculations - Fringe Surface Sediment
Benning Road Facility RI/FS Project
3400 Benning Rd, N.E., Washington DC 20019

Scenario Timeframe:	Current/Future
Medium:	Sediment
Exposure Medium/Point:	Surface Sediment

Exposure Route	Receptor Population	Receptor Age	Parameter Code	Parameter Definition	Unit	RME		CTE		Chronic Daily Intake (CDI) Equation
						Value	Rationale/ Reference	Value	Rationale/ Reference	

Notes:

RME = Reasonable Maximum Exposure; CTE = Central Tendency Exposure
-- Constituent-specific value.
(a) On days when the receptor is assumed to have direct contact with Anacostia River fringe surface sediment, one-half of the receptor's total daily ingestion exposure to outdoor soil/fringe surface sediment is assumed to come from the River, and the other half while away from the River (i.e., at home, work, school).

Table 5-5

Values Used for Daily Intake Calculations - Surface Water

Benning Road Facility RI/FS Project

3400 Benning Rd, N.E., Washington DC 20019

Scenario Timeframe:	Current/Future
Medium:	Surface Water
Exposure Medium/Point:	Surface Water

Exposure Route	Receptor Population	Receptor Age	Parameter Code	Parameter Definition	Unit	RME		CTE		Chronic Daily Intake (CDI) (Ingestion) Dermal Absorbed Dose (DAD) Equations
						Value	Rationale/ Reference	Value	Rationale/ Reference	

Notes:

RME = Reasonable Maximum Exposure; CTE = Central Tendency Exposure

-- Constituent-specific value.

(a) Extended periods of swimming in the Anacostia River are unlikely (see text). An upper-bound estimate of swimming event duration is estimated to be 30 minutes; the central tendency estimate is one-half of RME or 15 minutes.

(b) Anglers may occasionally wade in the river while fishing. An upper-bound estimate of wading duration while fishing is estimated to be 1 hour; the central tendency estimate is one-half of RME or 30 minutes.

(c) Visitors to the river may occasionally wade along the shoreline. An upper-bound estimate of wading while visiting/recreating is estimated to be 1 hour; the central tendency estimate is one-half of RME or 30 minutes.

Sources:

Dorevitch, S. et al. 2011. Water ingestion during water recreation. Water Research 45(5):2020-8.

Authors cite mean of 3-4 mL and upper confidence level estimate of 10-15 mL for limited contact recreational exposures to surface water (e.g., canoeing, kayaking, fishing, motor boating and rowing).

The midpoint of the upper confidence level rate (13 mL) is selected as the RME rate and the mean is selected as the CTE rate. As this is a per event rate, an hourly rate is not provided.

			FIR	Ingestion Rate of Fish	g/day	20	Gibson & McClafferty, 2005. (Washington DC area anglers) See Table 5-5 for details on ingestion rate derivation.	10	Gibson & McClafferty, 2005. (Washington DC area anglers) See Table 5-5 for details on ingestion rate derivation.	
			FI	Fraction from source	unitless	0.5	Assumes half of consumed catch is from Anacostia River in vicinity of site	0.25	1/2 of RME (assumes anglers eat catch from various locations throughout the Wash DC area)	
			Loss	Cooking Loss	g/g	--	--	--	--	
			EF	Exposure Frequency	days/year	365	FIR rate prorated over one year	365	FIR rate prorated over one year	
			ED	Exposure Duration	years	20	USEPA, 2014. 26 years total (20 adult/6 child)	10	USEPA, 2011 (Table ES-1). Average 12 yrs (10 adult/2 child)	
			CF	Conversion Factor	kg/g	0.001	1 kg = 0.001 mg	0.001	1 kg = 0.001 mg	
			BW	Body Weight	kg	80	USEPA, 2014	80	USEPA, 2014	
			AT-C	Averaging Time (Cancer)	days	25550	70-year lifetime x 365 days/year	25550	70-year lifetime x 365 days/year	
			AT-N	Averaging Time (Noncancer)	days	7300	ED (years) x 365 days/year	3650	ED (years) x 365 days/year	
			IF-C	Intake factor, cancer	(kg-fish)/(kg-bw/d)	3.57E-05	IF-C x CFF x (1-Loss) = CDI-C	4.46E-06	IF-C x CFF x (1-Loss) = CDI-C	
			IF-NC	Intake factor, noncancer	(kg-fish)/(kg-bw/d)	1.25E-04	IF-NC x CFF x (1-Loss) = CDI-NC	3.13E-05	IF-NC x CFF x (1-Loss) = CDI-NC	

Table 5-6
Values Used for Daily Intake Calculations - Fish Tissue
Benning Road Facility RI/FS Project
3400 Benning Rd, N.E., Washington DC 20019

Scenario Timeframe:	Current/Future
Medium:	Fish tissue
Exposure Medium/Point:	Fish tissue (fillet)

Exposure Route	Receptor Population	Receptor Age	Parameter Code	Parameter Definition	Unit	RME		CTE		Chronic Daily Intake (CDI) Equation
						Value	Rationale/ Reference	Value	Rationale/ Reference	

Notes:

RME = Reasonable Maximum Exposure; CTE = Central Tendency Exposure

-- Constituent-specific value; CFF (concentration in fish tissue) is also species-specific.

Notes:
CAS - Chemical Abstracts Service.
TCDD - 2,3,7,8-Tetrachlorodibenzo-p-dioxin.
TEQ - Toxicity Equivalence.
(a) USEPA, 2004. Exhibit B-3 (Organics). Values calculated based the equations below may have rounding different from that presented in Exhibit B-3.
(b) USEPA, 2004. Exhibit 3-1. (Inorganics)
(c) Default for all other inorganics.
(e) USEPA, 2004. Equation A-4. Default value.
(f) USEPA, 2004. Exhibit B-2. Value for hexachlorobiphenyl used for PCBs.

Equations:
USEPA, 2004. Risk Assessment Guidance for Superfund. Volume 1, Part E, Supplemental Guidance for Dermal Risk Assessment

Equation 3.8:	$\text{Log Kp} = -2.80 + 0.66 \log \text{Kow} - 0.0056\ \text{MW}$
Equation A.1:	$B = Kp \times MW^{0.5}/2.6$
Equation A.2:	Log Dsc/lsc = -2.8-0.0056 MW, where lsc = 1E-3 cm. Solving for Dsc: $Dsc = 10^{-2.8-0.0056\ MW} * lsc$.
Equation A.4:	$\tau = lsc^2/(6*Dsc)$
Equation A.5:	If $B \leq 0.6$, Equation A.5: $t^* = 2.4*\tau$
Equation A.6:	If B> 0.6: $t^* = (b - (b^2-c^2)^{0.5}) * l^2sc/(Dsc)$
Equation A-7:	$b = (2*(1+B)^2/\pi) - c$
Equation A-8:	$c = (1+3B+3B^2)/(3*(1+B))$

Definitions:
B - Relative Contribution of Permeability Coefficient.
Dsc - Effective diffusion coefficient through stratum corneum.
FA - Fraction Absorbed.
Kow - Octanol-Water Partition Coefficient.
Kp - Dermal Permeability Coefficient.
lsc - Apparent thickness of stratum corneum.
MW - Molecular Weight.
τ - lag time (hr/event).
t* - Time to reach steady state.

Table 5-9
Cooking Loss Factors for Fish Tissue
Benning Road Facility RI/FS Project

Hexachlorobenzene	118-74-1	0.1	0.32
Mirex	2385-85-5	0.1	0.32
Oxychlordane	27304-13-8	0.1	0.32
trans-Nonachlor	39765-80-5	0.1	0.32
PCBs			
Total PCBs	1336-36-3	0.13	0.3

Notes:
CTE - Central Tendency Exposure.
PCBs - Polychlorinated biphenyls.
RME - Reasonable Maximum Exposure.
TCDD - 2,3,7,8-Tetrachlorodibenzo-p-dioxin.
TEQ - Toxicity Equivalence.

(a) Fraction of mass loss values reported in 17 studies for various species and cooking methods (see Section 5.4.4 and Attachment D).
(b) For the RME scenario, the 10th percentile value is used.
(c) For the CTE scenario, the median value is used.

Exposure Point	Chemical of Potential Concern	Frequency of Detection	Arithmetic (1) Mean (mg/kg)	95% UCL (2) (mg/kg)	UCL Basis	Maximum Concentration (mg/kg)	Exposure Point Concentration (RME)			
							Value	Units	Statistic (3)	Rationale

Notes:

EPC - Exposure Point Concentration.
NC - Not Calculated.
ND - Not Detected in this area.
PCB - Polychlorinated Biphenyl.
RME - Reasonable Maximum Exposure.
SVOC - Semivolatile Organic Compound
TCDD-TEQ - 2,3,7,8-Dioxin-Toxicity Equivalence.
TPH - Total Petroleum Hydrocarbon
UCL - Upper confidence limit.

(1) Arithmetic mean. For datasets with non-detects, ProUCL Version 5.1 used the Kaplan-Meier method to handle detection limits.
(2) 95% Upper Confidence Limit (UCL) on the arithmetic mean concentration calculated using USEPA ProUCL Version 5.1. The UCL suggested by ProUCL is used, unless otherwise noted. In cases where more than one UCL is suggested, the higher UCL is used, unless otherwise noted. Where too few samples or detects are available, the 95% UCL is not calculated. See text for details.
(3) The EPC is equal to the 95% UCL where a sufficient number of samples and/or detects are available. The EPC is equal to the maximum detected concentration where a sufficient number of samples and/or detects are not available to calculate a UCL. See text for details.
(4) The 95% UCL exceeded the maximum detected concentration or was not calculated due to small sample size, and the maximum detected concentration was selected as the EPC.
(5) ProUCL recommended the H-Stat UCL. Alternate UCL selected based on ProUCL technical guidance and review of data.

CTE - Central Tendency Exposure.
EPC - Exposure Point Concentration.
NC - Not Calculated.
ND - Not Detected in this area.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile Organic Compound
TCDD-TEQ - 2,3,7,8-Dioxin-Toxicity Equivalence.
TPH - Total Petroleum Hydrocarbon
UCL - Upper confidence limit.
(1) Arithmetic mean. For datasets with non-detects, ProUCL Version 5.1 used the Kaplan-Meier method to handle detection limits.
(2) The EPC is the detected concentration for datasets with only one detected result. The EPC is the arithmetic mean for datasets with multiple detects, calculated as described above, in footnote (1).

Exposure Point	Chemical of Potential Concern	Frequency of Detection	Arithmetic [1] Mean (mg/kg)	95% UCL [2] (mg/kg)	UCL Basis	Maximum Concentration (mg/kg)	Exposure Point Concentration (RME)			
							Value	Units	Statistic [3]	Rationale

Notes:

EPC - Exposure Point Concentration.

PCB - Polychlorinated Biphenyl.

NC - Not Calculated.

ND - Not Detected in this area.

RME - Reasonable Maximum Exposure.

SVOC - Semivolatile Organic Compound

TCDD-TEQ - 2,3,7,8-Dioxin-Toxicity Equivalence.

TPH - Total Petroleum Hydrocarbon

UCL - Upper confidence limit.

(1) Arithmetic mean. For datasets with non-detects, ProUCL Version 5.1 used the Kaplan-Meier method to handle detection limits.

(2) 95% Upper Confidence Limit (UCL) on the arithmetic mean concentration calculated using USEPA ProUCL Version 5.1. The UCL suggested by ProUCL is used, unless otherwise noted. In cases where more than one UCL is suggested, the higher UCL is used, unless otherwise noted. Where too few samples or detects are available, the 95% UCL is not calculated. See text for details.

(3) The EPC is equal to the 95% UCL where a sufficient number of samples and/or detects are available. The EPC is equal to the maximum detected concentration where a sufficient number of samples and/or detects are not available to calculate a UCL. See text for details.

(4) The 95% UCL exceeded the maximum detected concentration or was not calculated due to small sample size, and the maximum detected concentration was selected as the EPC.

(5) ProUCL recommended the H-Stat UCL. Alternate UCL selected based on ProUCL technical guidance and review of data.

Notes:

CTE - Central Tendency Exposure.

EPC - Exposure Point Concentration.

NC - Not Calculated.

ND - Not Detected in this area.

PCB - Polychlorinated Biphenyl.

SVOC - Semivolatile Organic Compound

TCDD-TEQ - 2,3,7,8-Dioxin-Toxicity Equivalence.

TPH - Total Petroleum Hydrocarbon

UCL - Upper confidence limit.

(1) Arithmetic mean. For datasets with non-detects, ProUCL Version 5.1 used the Kaplan-Meier method to handle detection limits.

(2) The EPC is the detected concentration for datasets with only one detected result. The EPC is the arithmetic mean for datasets with multiple detects, calculated as described above, in footnote (1).

	Vinyl Chloride	ND	--	--	--	--	ND	--	--	--

Notes:

EPC - Exposure point concentration.

NC - Not Calculated; A sufficient number of samples is not available to calculate a UCL.

ND - Not Detected in this area.

RME - Reasonable maximum exposure.

VOC - Volatile Organic Compound.

UCL - Upper confidence limit.

(1) Arithmetic mean. For datasets with non-detects, ProUCL Version 5.1 used the Kaplan-Meier method to handle detection limits.

(2) 95% Upper Confidence Limit (UCL) on the arithmetic mean concentration calculated using USEPA ProUCL Version 5.1. The UCL suggested by ProUCL is used, unless otherwise noted. In cases where more than one UCL is suggested, the higher UCL is used, unless otherwise noted. Where too few samples or detects are available, the 95% UCL is not calculated.

(3) The EPC is equal to the 95% UCL where a sufficient number of samples and/or detects are available. The EPC is equal to the maximum detected concentration where a sufficient number of samples and/or detects are not available to calculate a UCL. Statistic: Maximum Detected Value (Max); 95% UCL (95% UCL).

(4) The 95% UCL exceeded the maximum detected concentration or was not calculated, and the maximum detected concentration was selected as the EPC.

Notes:

EPC - Exposure Point Concentration.
PCB - Polychlorinated Biphenyl.
RME - Reasonable Maximum Exposure.
SVOC - Semivolatile Organic Compound
TCDD-TEQ - 2,3,7,8-Dioxin-Toxicity Equivalence.
TPH - Total Petroleum Hydrocarbon
UCL - Upper confidence limit.

(1) Arithmetic mean. For datasets with non-detects, ProUCL Version 5.1 used the Kaplan-Meir method to handle detection limits.
(2) 95% Upper Confidence Limit (UCL) on the arithmetic mean concentration calculated using USEPA ProUCL Version 5.1. The UCL suggested by ProUCL is used, unless otherwise noted. In cases where more than one UCL is suggested, the higher UCL is used, unless otherwise noted. Where too few samples or detects are available, the 95% UCL is not calculated. See text for details.
(3) The EPC is equal to the 95% UCL where a sufficient number of samples and/or detects are available. The EPC is equal to the maximum detected concentration where a sufficient number of samples and/or detects are not available to calculate a UCL. See text for details.
(4) EPCs calculated based on fringe surface sediment samples available for exposure by human receptors. See text.
(5) ProUCL recommended the H-Stat UCL. Alternate UCL selected based on ProUCL technical guidance and review of data.

	PCBs									
	Total PCBs	--	--	--	--	--	9.40E-03	ug/L	Lowest RL	Footnote (5)

Notes:

EPC - Exposure point concentration.

PCB - Polychlorinated Biphenyl.

RL - Reporting Limit.

RME - Reasonable maximum exposure.

TCDD-TEQ - 2,3,7,8-Dioxin-Toxicity Equivalence.

UCL - Upper confidence limit.

(1) Arithmetic mean. For datasets with non-detects, ProUCL Version 5.1 used the Kaplan-Meir method to handle detection limits.

(2) 95% Upper Confidence Limit (UCL) on the arithmetic mean concentration calculated using USEPA ProUCL Version 5.1. The UCL suggested by ProUCL is used, unless otherwise noted. In cases where more than one UCL is suggested, the higher UCL is used, unless otherwise noted. Where too few samples or detects are available, the 95% UCL is not calculated. See text for details.

(3) The EPC is equal to the 95% UCL where a sufficient number of samples and/or detects are available. The EPC is equal to the maximum detected concentration where a sufficient number of samples and/or detects are not available to calculate a UCL. See text for details.

(4) The 95% UCL exceeded the maximum detected concentration or was not calculated due to small sample size, and the maximum detected concentration was selected as the EPC.

(5) PCBs were not detected in Anacostia River surface water samples analyzed via Method 8082. Historical data analyzed via EPA 1668 suggest much lower concentrations in the 1 to 5 ng/L range. However, the lowest reporting limit (RL) for Method 8082 has been used, which is highly conservative.

Notes:

EPC - Exposure point concentration.

NC - Not Calculated; a sufficient number of samples and/or detects is not available to calculate a UCL.

PCB - Polychlorinated Biphenyl.

PCB-TEQ - Polychlorinated Biphenyl Toxicity Equivalence.

RME - Reasonable maximum exposure.

TCDD-TEQ - 2,3,7,8-Dioxin-Toxicity Equivalence.

UCL - Upper confidence limit.

(1) Arithmetic mean. For datasets with non-detects, ProUCL Version 5.1 used the Kaplan-Meir method to handle detection limits.

(2) 95% Upper Confidence Limit (UCL) on the arithmetic mean concentration calculated using USEPA ProUCL Version 5.1. The UCL suggested by ProUCL is used, unless otherwise noted. In cases where more than one UCL is suggested, the higher UCL is used, unless otherwise noted. Where too few samples or detects are available, the 95% UCL is not calculated. See text for details.

(3) The EPC is equal to the 95% UCL where a sufficient number of samples and/or detects are available. The EPC is equal to the maximum detected concentration where a sufficient number of samples and/or detects are not available to calculate a UCL. See text for details.

(4) The 95% UCL exceeded the maximum detected concentration or was not calculated, and the maximum detected concentration was selected as the EPC.

(5) Organic and inorganic arsenic calculated assuming 90% of total arsenic is organic, and 10% is inorganic (FDA, 1993, Pinkney, 2017).

(6) The samples collected in the Upper Anacostia River are assumed to reflect overall conditions within the several mile long river reach that was sampled (or the possibly larger home range for some of the fish species sampled), and may not reflect the specific conditions within the Waterside Investigation Area.

Notes:

CTE - Central tendency exposure.

EPC - Exposure point concentration.

J - The chemical was positively identified; however, the associated numerical value is an estimated concentration.

+/- - Indicates the result may be biased high/low.

NC - Not Calculated; a sufficient number of samples and/or detects is not available to calculate a UCL.

PCB - Polychlorinated Biphenyl.

PCB-TEQ - Polychlorinated Biphenyl Toxicity Equivalence.

TCDD-TEQ - 2,3,7,8-Dioxin-Toxicity Equivalence.

UCL - Upper confidence limit.

(1) Arithmetic mean. For datasets with non-detects, ProUCL Version 5.1 used the Kaplan-Meir method to handle detection limits.

(2) The EPC is the detected concentration for datasets with only one detected result. The EPC is the arithmetic mean for datasets with multiple detects.

(3) Organic and inorganic arsenic calculated assuming 90% of total arsenic is organic, and 10% is inorganic (FDA, 1993, Pinkney, 2017).

(4) The samples collected in the Upper Anacostia River are assumed to reflect overall conditions within the several mile long river reach that was sampled (or the possibly larger home range for some of the fish species sampled), and may not reflect the specific conditions within the Waterside Investigation Area.

Table 5-22
Derivation of Particulate Emission Factor for the Surface Soil to Outdoor Air Pathway (non-excavation pathway)
Benning Road Facility RI/FS Project
3400 Benning Rd, N.E., Washington DC 20019

Parameter	Definition	Units	Value	Notes
A_c	Areal extent of site	acres	77	Site-specific
A	Dispersion modeling constants (Philadelphia, PA)	unitless	14.0111	USEPA 2002, Exhibit D-2
B			19.6154	
C			225.3397	
Q/C_{wind}	Dispersion Factor - Inverse of mean concentration at center of source	g/m^2-s per kg/m^3	39.44	USEPA 2002, Equation D-1
V	Fraction of vegetative cover	unitless	0.5	USEPA, 2002 Default Value Equation 4-5
U_m	Mean annual windspeed	m/s	4.69	
U_t	Equivalent threshold value of windspeed at 7 m	m/s	11.32	
F(x)	Function dependent on U_m/U_t	unitless	0.194	
PEF	**Particulate emission factor**	**m^3/kg**	**5.72E+08**	USEPA 2002, Equation 4-5

Equations:

Equation D-1

$$Q/C_{wind} = A \times \exp\left[\frac{(\ln A_c - B)^2}{C}\right]$$

Equation 4-5

$$PEF(m^3/kg) = \frac{Q/C_{wind}(3600 s/h)}{0.036(1-V)(U_m/U_t)^3 F(x)}$$

Notes:
EPC - Exposure Point Concentration.
ND - Not Detected in this area.
PCB - Polychlorinated Biphenyl.
PEF - Particulate Emission Factor.
RME - Reasonable Maximum Exposure.
SVOC - Semivolatile Organic Compound
TCDD-TEQ - 2,3,7,8-Dioxin-Toxicity Equivalence.
TPH - Total Petroleum Hydrocarbon
(1) Estimated outdoor air EPCs were calculated by dividing the surface soil RME EPC by the PEF for the non-excavation scenario. See report text for details.

Table 5-25
Exposure Point Concentration Summary — Surface Soil to Outdoor Air - Non-Excavation Scenario (RME)
Central Tendency Exposure
Benning Road Facility RI/FS Project
3400 Benning Rd, N.E., Washington DC 20019

Scenario Timeframe: Current/Future
Medium: Surface Soil (0-1 foot)
Exposure Medium: Soil

Chemical of Potential Concern	Hypothetical Future Park Land/Green Space		Warehouse and Laydown Area		Salvage Yard and Waste Storage Area		Stores and Fleet Maintenance Area		Offices and Parking Lot		Substation #7		Transformer Shop		Vehicle Refueling Area

Notes:
EPC - Exposure Point Concentration.
ND - Not Detected in this area.
PCB - Polychlorinated Biphenyl.
PEF - Particulate Emission Factor.
RME - Reasonable Maximum Exposure.
SVOC - Semivolatile Organic Compound
TCDD-TEQ - 2,3,7,8-Dioxin-Toxicity Equivalence.
TPH - Total Petroleum Hydrocarbon
(1) Estimated outdoor air EPCs were calculated by dividing the soil RME EPC by the PEF for the excavation scenario. See report text for details.

Table 5-27

Table 5-30
Evaluation of the Groundwater to Surface Water Migration Pathway
Benning Road Facility RI/FS Project
3400 Benning Rd, N.E., Washington DC 20019

Notes:
All units are in microgram per liter (ug/L).
CAS - Chemical Abstracts Service.
DAF - Dilution Attenuation Factor.
EN - Essential Nutrient.
HH - Human health.
J - The chemical was positively identified; however, the associated numerical value is an estimated concentration.
+/- Likely to have a high (+) or low (-) bias.
NA - Not analyzed.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
TCDD TEQ - Dioxin toxicity equivalence.
VOC - Volatile organic compound.
U - Not detected above the laboratory reporting limit.
UJ - Not detected above laboratory reporting limit; Estimated value.
USEPA - United States Environmental Protection Agency.

(a) Only chemicals detected at least once in nearshore groundwater monitoring wells are presented. For TCDD-TEQ, pesticides, SVOCs, and VOCs 2016 groundwater data were used, where available (See Section 5.6 of the text). Otherwise data collected in 2014 was used, such that for each chemical and well combination, the most recent data point is presented. The RI Report presents 2016 and 2016 data for all wells/chemicals.
(b) Surface water screening levels were selected based on the following hierarchy:
1. District Department of the Environment. Title 21 of the District of Columbia Municipal Regulations, Chapter 11, Water Quality Standards. Effective November 1, 2013.
2. USEPA National Recommended Water Quality Criteria for Priority Pollutants. Value for Human Health for the consumption of organisms. Accessed September 2017.
3. USEPA Regional Screening Level for Tapwater based on 1x10-6 target risk level and target hazard quotient of 0.1. May 2018.
See Table 3-11 for surface water screening levels and surrogates used.
(c) Surface water concentrations were estimated by multiplying groundwater results from the nearshore monitoring wells by a site-specific dilution attenuation factor (DAF). DAFs were derived separately for the upper and lower aquifers as further discussed in the Remedial Investigation Report and shown in Attachment F of the BHHRA report.

Notes:
Values are presented to one significant figure.

NA - Not Applicable; no dose-response value.
NC - Not calculated.
NCOPC - Not a Chemical of Potential Concern in this media.

(a) Calculated based on data from Pinkney (2017). The samples collected in the Upper Anacostia River are assumed to reflect overall conditions within the several mile long river reach that was sampled (or the possibly larger home range for some of the fish species sampled), and may not reflect the specific conditions within the Waterside Investigation Area.
(b) Total (includes Total PCBs for fringe surface sediment, surface water, and fish).
(c) Total (includes Total PCBs for fringe surface sediment and surface water and PCB-TEQ for fish).

Notes:
Values are presented to one significant figure.

NA - Not Applicable; no dose-response value.
HI - Hazard Index.
NC - Not calculated.

NCOPC - Not a Chemical of Potential Concern in this media.
TE - Target Endpoint.

(a) Calculated based on data from Pinkney (2017). The samples collected in the Upper Anacostia River are assumed to reflect overall conditions within the several mile long river reach that was sampled (or the possibly larger home range for some of the fish species sampled), and may not reflect the specific conditions within the Waterside Investigation Area.
(b) Total (includes Total PCBs for fringe surface sediment, surface water, and fish).
(c) Total (includes Total PCBs for fringe surface sediment and surface water and PCB-TEQ for fish).
(d) See Attachment H.

Notes:
NA - Not Applicable; no dose-response value.
NC - Not calculated.
NCOPC - Not a Chemical of Potential Concern in this media.

Values are presented to one significant figure.
(a) The young child is assumed to not accompany the adult or older child anglers on fishing trips to the river, but is assumed to eat river fish that is brought home.
(b) Total Receptor Risk/Hazard based on all COPCs except PCB-TEQ.
(c) Total Receptor Risk/Hazard based on all COPCs except Total PCBs.
(d) Tissue samples from the tidal Anacostia and Potomac Rivers were analyzed for individual chlordane isomers, and tissue samples from the Non-Tidal Anacostia River were analyzed for Chlordane (technical).

Notes:
NA - Not Applicable; no dose-response value.
NC - Not calculated.
NCOPC - Not a Chemical of Potential Concern in this media.

Values are presented to one significant figure.
(a) The young child is assumed to not accompany the adult or older child anglers on fishing trips to the river, but is assumed to eat river fish that is brought home.
(b) Total Receptor Risk/Hazard based on all COPCs except PCB-TEQ.
(c) Total Receptor Risk/Hazard based on all COPCs except Total PCBs.
(d) See Attachment H.
(e) Tissue samples from the tidal Anacostia and Potomac Rivers were analyzed for individual chlordane isomers, and tissue samples from the Non-Tidal Anacostia River were analyzed for Chlordane (technical).

Minimum	0.045	0.03	0.3
Maximum	520000	8800	59.1
Mean	16925	300	4.7
Median	2	1.20	1.5

Notes:
Soil samples collected at depths greater than 16 feet bgs were not included in the BHHRA data set.
PCB - Polychlorinated Biphenyl.
(a) Sample collected beneath an obstruction (e.g., concrete or pavement). Sample depth measured from top of slab. Sample was collected immediately below slab and is therefore considered surface soil for potential future exposures.

Exposure Areas:

Maintenance: Stores and Fleet Maintenance Area
Salvage: Salvage Yard and Waste Storage Area
Substation #7: Substation #7
Transformer Shop: Transformer Shop
Vehicle Refueling: Vehicle Refueling Area
Warehouse: Warehouse and Laydown Area

Notes:

(a) The samples collected in the Upper Anacostia River are assumed to reflect overall conditions within the several mile long river reach that was sampled (or the possibly larger home range for some of the fish species sampled), and may not reflect the specific conditions within the Waterside Investigation Area.

Source: Pinkney, A.E. 2017. Analysis of contaminant concentrations in fish tissue collected from the waters of the District of Columbia. Final Report. CBFO-C14-03. U.S. Fish and Wildlife Service, Chesapeake Bay Field Office, Annapolis, MD. 9/2014. Revised 11/2017.

Attachment B

Screening Level Evaluation of the Vapor Intrusion Pathway

Attachment B
Screening Level Evaluation of the Vapor Intrusion Pathway

A screening level evaluation of the potential for vapors in the subsurface to migrate to indoor air (the vapor intrusion pathway) is provided below. The evaluation was conducted for all areas of the Site, regardless of the presence of buildings, in order to provide a conservative evaluation of potential current and future risk.

Extensive soil sampling was conducted at the Site, including analysis of volatile organic compounds (VOCs) on over 200 samples. VOCs were detected infrequently (in about 10% of the samples). Vapor intrusion screening levels for soil are not available from the United States Environmental Protection Agency (USEPA) or the District of Columbia Department of Energy and Environment (DOEE) because soil is not considered an appropriate medium for evaluation of vapor intrusion. Therefore, the vapor intrusion pathway was evaluated based on groundwater data.

As discussed in the of the main text of this Remedial Investigation Report, the Patapsco Formation underlying the Site is divided by a semi-confining layer into an upper water-bearing zone (UWZ) and a lower water-bearing zone (LWZ). The water table aquifer (UWZ) generally ranges from 9 to 16 feet (ft) below ground surface (bgs), but reaches as deep as 26 ft bgs in the vicinity of the topographic high in the south-central portion of the Site. The piezometric surface of the LWZ aquifer at the Site generally averages 0 to 2 ft deeper than the UWZ water table. Groundwater samples were collected from monitoring wells and direct-push borings from both the UWZ and LWZ. Depending on the analyte, up to 117 samples are available from the UWZ and up to 66 samples are available from the LWZ; all available samples were analyzed for VOCs. This vapor intrusion evaluation is based on the shallower UWZ.

VISL Screen

USEPA's Vapor Intrusion Screening Level (VISL)[1] calculator was used to derive groundwater screening levels for the vapor intrusion pathway. VISLs are applicable to chemicals that are volatile (defined by the VISL calculator as those chemicals with a Henry's Law constant greater than 10^{-5} atm-m^3/mole and a vapor pressure greater than one millimeter of mercury) and for which inhalation toxicity data are available. As indicated in Table B-1, 30 of the organic chemicals detected in groundwater meet these criteria. VISLs were derived using the VISL calculator's default exposure assumptions for an industrial scenario (8 hours per day, 250 days per year for 25 years). A target cancer risk level of $1x10^{-6}$ and a target hazard quotient of 0.1 were used. The VISL calculator uses a default groundwater-to-indoor air attenuation factor of 0.001, which is recommended by USEPA as a reasonably conservative generic attenuation factor (USEPA, 2015a). The resulting groundwater VISLs are therefore conservative. An exceedance of a VISL does not necessarily

[1] https://www.epa.gov/vaporintrusion/vapor-intrusion-screening-level-calculator. Accessed February 2019.

indicate an unacceptable risk from the vapor intrusion pathway, but rather that further evaluation is warranted.

Maximum detected VOC concentrations in UWZ groundwater were compared to the VISLs in Table B-2. The following chemicals were found to have maximum detected concentrations greater than VISLs:

Chemical	Upper Water-Bearing Zone
Chloroform	X
Tetrachloroethylene (PCE)	X
Trichloroethene (TCE)	X
Vinyl Chloride	X
Diesel Range Organics (C10-C20) (DRO)	X

Each of these chemicals is evaluated below to select Chemicals of Potential Concern (COPCs) for further evaluation in this screening level vapor intrusion evaluation.

Chloroform

Chloroform was detected sporadically in Site wells, with only one exceedance of the VISL (3.55 micrograms per liter [µg/L]) in the UWZ; detection limits are below the VISL. The exceedance occurred in well DP60, along the northern property boundary, at a depth of 15 to 20 feet bgs (15 µg/L). There are no permanent buildings in this area, making the vapor intrusion pathway incomplete under the current scenario. Given the depth to groundwater, considerable attenuation is expected to occur in the vadose zone. The tight soils in this vicinity further reduce soil permeability and limit vapor migration. However, chloroform was conservatively selected as a COPC for the potential future vapor intrusion scenario.

TCE, PCE, and Vinyl Chloride

Areas where TCE, PCE, and vinyl chloride exceeded VISLs are co-located and are limited to two general areas: one along the southern boundary and another on the downgradient perimeter in the southwest area of the Site. There are no permanent buildings in these areas, making the vapor intrusion pathway incomplete under the current scenario.

Wells with exceedances of TCE and PCE along the southern boundary adjacent to Benning Road include DPA3, DPA4, DPA5, DPB3, DPB5, DPB6, DPB7, DPB9, DPB10 (PCE only), DPC4, DPC5, DPC7, SUSDP09, and MW-09A. Vinyl chloride also exceeded its VISL in MW-09A. Detected concentrations of TCE in these wells ranged from less than 1 µg/L to 41 µg/L (MW-09A); the VISL for TCE is 2.2 µg/L. Detected concentrations of PCE in these wells ranged from less than 1 µg/L to 470 µg/L (DPB7); the VISL for PCE is 24.2 µg/L. Vinyl chloride was not detected in the majority of these wells at a reporting limit of 1 µg/L, which is lower than the VISL of 2.45 µg/L. One detected concentration in MW-09A exceeded the VISL at a concentration of 5.3 µg/L.

Wells in the UWZ with exceedances of TCE and PCE at the downgradient perimeter adjacent to Anacostia Avenue include SUSDP09, TA19C1, and TA19C2. Detected concentrations of TCE in these wells ranged from less than 1 µg/L to 5.9 µg/L (TA19C2) and detected concentrations of PCE ranged from less than 1 µg/L to 30 µg/L (TA19C1). As mentioned, the VISL is 2.2 µg/L for TCE and 24.2 µg/L for PCE.

TCE also exceeded the VISL in MW-05, located between the two general areas identified above. However, the concentration of 2.3 µg/L is only marginally greater than the VISL of 2.2 µg/L.

Given the depth to groundwater in these areas, considerable attenuation is expected to occur in the vadose zone. The tight soils in this vicinity further reduce soil permeability and limit vapor migration. However, TCE, PCE, and vinyl chloride were conservatively selected as COPCs for the potential future vapor intrusion scenario.

DRO

DRO was detected in fewer than 10 groundwater samples at concentrations ranging from 270 µg/L to 540 µg/L. The VISL for DRO was derived using very conservative assumptions, including the use of a provisional screening toxicity value and volatility parameters based on n-nonane. The resulting VISL is less than 1 part per billion.

Both the forensic saturated hydrocarbon and DRO/oil range organics (ORO) chromatographic data indicate the highest concentrations of total petroleum hydrocarbon (TPH) on Site are likely from dielectric fluids, such as refined mineral oils used in transformers. Both the literature about dielectric fluids and previous analysis conducted by AECOM for Pepco indicate these severely hydrotreated naphthenic oils have extremely low aromatic content and consist primarily of aliphatic hydrocarbons in the C20-C40 range. Gasoline range organics (GRO) were not detected in the UWZ, and detections of benzene, toluene, ethylbenzene, and xylenes were below VISLs.

A key difference between vapor intrusion of chlorinated VOCs and petroleum hydrocarbons is biodegradation (ITRC, 2014; USEPA, 2015b). Biodegradation can reduce concentrations in the vadose zone thus reducing the potential for vapor intrusion by petroleum hydrocarbons. The Interstate Technology & Regulatory Council (ITRC) and USEPA vapor intrusion guidance documents established minimum vertical separation distances between a building foundation and the petroleum source of 5 feet (ITRC) and 6 feet (USEPA) for dissolved phase constituents and 18 feet (ITRC) and 15 feet (USEPA) for light non-aqueous phase liquid (LNAPL). Where the Site-specific vertical separation distance meets or exceeds the applicable minimum distance, petroleum hydrocarbons are expected to biodegrade to levels below those that would pose a health concern, and no further evaluation of the vapor intrusion pathway is considered necessary (ITRC, 2014; USEPA, 2015b). As the depth to groundwater is deeper than the separation distances, the vapor intrusion pathway is considered incomplete. Therefore, DRO was not included as a COPC for further evaluation in the vapor intrusion evaluation.

Further Evaluation of COPCs

The COPCs selected above were further evaluated to estimate the potential carcinogenic risk and noncarcinogenic hazard for an indoor commercial/industrial worker assuming a building is constructed in the future. USEPA's VISL calculator was used to derive the potential risk/hazard estimates based on maximum detected concentrations in each of the areas discussed above (see Table B-3). Potential risks and hazards were compared to USEPA target levels, as described below.

USEPA has established target risk levels under the National Contingency Plan (NCP) (USEPA, 1990). Target risk levels refer to levels of cancer risk or hazard indices that are deemed acceptable by the USEPA or other regulatory agencies. These are levels below which the potential for adverse effects to humans are assumed to be negligible or inconsequential. The NCP establishes a target cancer risk range of 10^{-6} to 10^{-4} and a target hazard index (HI) of less than or equal to 1 (USEPA, 1990). The USEPA subsequently clarified that, "Where the cumulative carcinogenic site risk to an individual based on reasonable maximum exposure for both current and future land use is less than 10^{-4}, and the non-carcinogenic hazard quotient is less than 1, action generally is not warranted, unless there are adverse environmental impacts" (USEPA, 1991). Potential chemicals of concern (COCs) are identified in this Baseline Human Health Risk Assessment, per DOEE request, as those COPCs with individual cancer risks greater than 1×10^{-6} or an HI greater than 1 on a target endpoint basis. The results are presented in the tables below.

COPC	Potential Cancer Risk			
	Southern Boundary [(a)]	Northern Boundary (DP60)	Downgradient Perimeter (TA19C1, TA19C2)	MW-05A
Chloroform	4E-07	4E-06	ND	2E-07
Tetrachloroethylene	7E-06	7E-09	5E-07	2E-07
Trichloroethylene	6E-06	ND	8E-07	3E-07
Vinyl Chloride	2E-06	ND	ND	ND
Total	**2E-05**	**4E-06**	**1E-06**	**8E-07**

Notes:
ND = Not detected.
Blue highlighting indicates that the cumulative potential risk is within USEPA's target risk range of 10^{-6} to 10^{-4}.
[(a)] Wells with exceedances: DPA3, DPA4, DPA5, DPB10, DPB3, DPB5, DPB6, DPB7, DPB9, DPC4, DPC5, DPC7, MW-09A, and SUSDP09.

COPC	Potential Noncancer Hazard Index (HI)			
	Southern Boundary [(a)]	Northern Boundary (DP60)	Downgradient Perimeter (TA19C1, TA19C2)	MW-05A
Chloroform	0.0005	0.005	ND	0.0003
Tetrachloroethylene	2	0.002	0.1	0.06
Trichloroethylene	2	ND	0.3	0.1
Vinyl Chloride	0.01	ND	ND	ND
Total	**4**	**0.007**	**0.4**	**0.2**

Notes:
ND = Not detected.
Yellow highlighting indicates that the target endpoint HI exceeds 1.
[(a)] Wells with exceedances: DPA3, DPA4, DPA5, DPB10, DPB3, DPB5, DPB6, DPB7, DPB9, DPC4, DPC5, DPC7, MW-09A, and SUSDP09.

The cumulative potential risk along the southern boundary, the northern boundary, and the downgradient perimeter is within the USEPA risk range of 10^{-6} to 10^{-4} (USEPA, 1991). The cumulative potential risk in MW-05A is below the risk range. These results indicate that the vapor intrusion pathway does not pose an inhalation risk in excess of USEPA target levels. The total noncancer HI along the southern boundary exceeds 1; the remaining areas have an HI below 1. COPCs with potential risks greater than 1×10^{-6} are indicated above in blue, and those with HI greater than 1 are indicated above in yellow.

Conclusions

Per the NCP, actions at Superfund sites are generally not warranted unless the total cumulative risk exceeds 10^{-4} or the HI exceeds 1 on a target endpoint basis. Based on the conservative screening level vapor intrusion evaluation and assuming a building is constructed in the future, potential cancer risks are within the risk range. Exceedances of a target endpoint HI of 1 occurred along the southern property boundary. At the request of DOEE, COPCs with potential risks above 10^{-6} were identified as potential COCs regardless of whether cumulative risk exceeded 10^{-4}. The table below presents the potential COCs with potential risks greater than 10^{-6} or a target endpoint HI of 1; the hazard value representing the highest target endpoint HI is presented.

COPC	Risk/HI	Potential COCs for the Future Vapor Intrusion Pathway [(a)]	
		Southern Boundary	Northern Boundary (DP-60)
Chloroform	Risk	--	4E-06
Tetrachloroethylene	Risk	7E-06	--
	HI	2	--
Trichloroethylene	Risk	6E-06	--
	HI	2	--
Vinyl Chloride	Risk	2E-06	--

Notes:
-- Indicates that the Excess Lifetime Cancer Risk is less than or equal to 10^{-6} or the HI is less than or equal to 1.
Blue highlighting indicates that risk exceeds 10^{-6} but is less than or equal to 10^{-4}.
Yellow highlighting indicates that risk exceeds 10^{-4} or the target endpoint HI exceeds 1.
[(a)] Future outdoor industrial worker.

Notes:
CAS - Chemical Abstracts Service.
COPC - Chemical of Potential Concern.
HSDB - Hazardous Substances Databank. https://toxnet.nlm.nih.gov/cgi-bin/sis/search2. Accessed February 2019.
NA - Not Applicable.
PCB - Polychlorinated biphenyl.
RAIS - Risk Assessment Information System. https://rais.ornl.gov/cgi-bin/tools/TOX_search?select=chem_spef. Accessed February 2019.
SVOC - Semivolatile Organic Compound.
TCDD-TEQ - Dioxin Toxic Equivalence.
TPH - Total Petroleum Hydrocarbons.
VISL - Vapor Intrusion Screening Level Calculator.
VOC - Volatile Organic Compound.

(a) - Chemical meets the definition of volatility if the Henry's law constant is greater than 1E-05 atm-m^3/mol or if the vapor pressure is greater than 1 millimeter mercury (mm Hg).
(b) - Chemical is evaluated for the vapor intrusion pathway if it meets the definiton of volatility and if it has inhalation toxicity data.
(c) - Calculated using VISL Calculator with default commercial/industrial parameters. Based on a cancer risk level of 1E-6 and an hazard quotient of 0.1. https://www.epa.gov/vaporintrusion/vapor-intrusion-screening-level-calculator. Accessed February 2019.

Notes:

(1) Minimum/maximum detected concentration and associated data flags.
J = The chemical was positively identified; however, the associated numerical value is an estimated concentration only.
(2) Lab Reporting Detection Limits (RDLs) are shown where the frequency of detection is less than 100%.
(3) Maximum detected concentration used for screening.
(4) Screening levels are equal to the USEPA Vapor Intrusion Screening Level based on a target risk level of $1x10^{-6}$ for carcinogens and a target hazard quotient of 0.1 for noncarcinogens. Calculated February 2019 via calculator.
See Table F-1 for screening levels and surrogates used.
(6) Rationale Codes:
Selection Reason: Above Screening Level (ASL)
Deletion Reason: Below Screening Level (BSL).

Definitions:

CAS - Chemical Abstracts Service
COPC - Chemical of Potential Concern
PCB - Polychlorinated biphenyl.
SVOC - Semivolatile Organic Compound.
TCDD TEQ - Dioxin Toxic Equivalence
TPH - Total Petroleum Hydrocarbons.
VOC - Volatile Organic Compound.

Attachment C

Discussion of Key Exposure Parameters Used in the BHHRA

Attachment C
Discussion of Key Exposure Parameters Used in the BHHRA

1 Introduction

This Baseline Human Health Risk Assessment (BHHRA) evaluated the following receptors:

Landside

- Current/Future Construction Worker (adult). Potential direct contact (ingestion and dermal) with surface and subsurface soil and potential inhalation of soil-derived fugitive dust during utility or other construction work requiring excavation. In addition, the construction worker may be exposed to volatiles in the air of an excavation trench due to volatilization from groundwater infiltrating the trench.
- Future Outdoor Industrial Worker (adult). Potential direct contact (ingestion and dermal) with surface soil and potential inhalation of surface soil-derived fugitive dust, in the event of a change in the existing soil cover on Site in the future.
- Future Indoor Industrial Worker (adult). A screening level evaluation of the potential vapor intrusion from groundwater to indoor air pathway is included in Attachment B. Default exposure parameters were used (exposure of 250 days per year for 25 years).
- Future Recreational Visitors (older child/teen). Potential direct contact (ingestion and dermal) with surface soil, and potential inhalation of surface soil-derived fugitive dust in the western portion of the Site next to Anacostia Avenue, if the area were to become publically accessible in the future (see Figure 3-1 of the main text of this BHHRA).

Waterside

- Current/Future Recreational Anglers (adult, older child/teen, young child). Potential direct contact with fringe surface sediment and surface water while fishing, and ingestion of fish from the Anacostia River. The BHHRA also included an evaluation of a high-end consuming angler for ingestion of fish only.
- Current/Future Swimmers (adult, older child/teen, young child). Potential direct contact with fringe surface sediment and surface water while swimming in the Anacostia River.

- Current/Future Waders (adult, older child/teen, young child). Potential direct contact with fringe surface sediment and surface water while wading in the Anacostia River.
- Shoreline Workers (adult). Potential direct contact with fringe surface sediment and surface water while performing maintenance, landscaping, or other activities along the shoreline of the Anacostia River.

Tables 5-2, 5-3, 5-4, 5-5, and 5-6 of the main text of this BHHRA present the exposure parameter values used to quantitatively estimate potential risks from exposures to soil, excavation trench air, fringe surface sediment, surface water, and fish tissue, respectively. Default exposure factors were used in the screening level vapor intrusion evaluation (8 hours per day, 250 days per year, 25 years). A description of each Landside receptor evaluated in the BHHRA is provided in Section 5.3 of the main text of this BHHRA. Key exposure parameters are discussed below for both the reasonable maximum exposure (RME) and central tendency exposure (CTE) scenarios, including:

- Fish Consumption Exposure Parameters
- Soil and Fringe Surface Sediment Ingestion Rates
- Surface Water Ingestion Rates
- Body Surface Areas Exposed
- Soil and Fringe Surface Sediment Adherence Factors
- Exposure Frequency
- Exposure Duration
- Body Weight

2 Fish Consumption Exposure Parameters

A number of parameters were used to calculate the potential risk from consumption of fish, including consumption rate, species, body parts consumed, fraction ingested from the Site, preparation and cooking methods, and years of fishing at the Site. In selecting appropriate fish consumption exposure parameters, U.S. Environmental Protection Agency (USEPA) guidance (USEPA, 1989a,b, 1998, 2000, 2011) discusses the importance of considering site-specific factors, including water quality, public access, abundance of desirable species, and proximity of other desirable water bodies, as well as characteristics of the angling population.

The Anacostia River is a tidal river with habitat suitable for a variety of freshwater and estuarine species, including American eel, brown bullhead, channel catfish, largemouth and smallmouth bass, carp, and sunfish. Angling from shore and boat has been observed, as discussed below. A water body-specific fish consumption advisory is in effect for the Anacostia and Potomac Rivers recommending against consumption of some species (catfish, carp, and American eel) and limited consumption of other species (e.g., largemouth bass and sunfish) (DOEE, 2016). However, some people may not be aware of the advisory, or may choose to catch and eat river fish despite the advisory.

To aid in the development of appropriate fish consumption exposure parameters for the BHHRA, available local and regional angler studies were consulted. Fish consumption rates and fraction of diet/fraction ingested are discussed below.

2.1 Fish Consumption Rate

Available angler surveys were reviewed to identify data that could serve as a source of consumption rates for the Anacostia River. Four regional studies were identified, and are summarized below.

- Survey of Chesapeake Bay Occupational and Recreational Fishers (Harris et al., 2009)
- Chesapeake Bay Angler Survey (Gibson and McClafferty, 2005)
- Anacostia River Angler Survey (OpinionWorks, 2012)
- Subsistence Fishing on the Potomac and Anacostia Rivers (NPS, 2016)

Chesapeake Bay Occupational and Recreational Fishers Survey

Researchers from the University of Toronto and Virginia Commonwealth University, with support from the Virginia Department of Health, conducted a survey of occupational and recreational anglers that fish in Chesapeake Bay (Harris et al., 2009). The participants (n=99) were recruited from an existing cohort of an epidemiological study examining exposure to a seafood toxin (*Pfiesteria*), and included occupational anglers as well as recreational anglers with occupations not related to fishing. The majority (80%) were male, 85% had at least a high school education, and 98% were white (2% were black). In 2001, participants were administered an in-person questionnaire that focused on current fish consumption, species consumed, past fish consumption, and perceptions of risk. Fish consumption included all sources of fish meals, including store-bought, self-caught, restaurant, etc. Information on fish meal frequency was solicited two ways: 1) on the basis of average fish consumption on a weekly, monthly, or annual basis, and 2) on a species-specific basis. Using the two methods, the median number of annual fish meals was estimated to be 52 based on “average” reported fish meal frequency, and 65 based on summing species-specific reported fish meal frequencies. Species most frequently consumed included flounder, tuna (including canned tuna), striped bass, sea trout, and croaker. Approximately 70% of the fish consumed was self-caught (with about half of that from Virginia waters), and the average fish meal size was approximately 9 ounces (median of 8 ounces). The authors found a statistically significant relationship between consumption and occupation, with higher consumption by occupational anglers and other water-related occupations versus non-water-related occupations. The authors suggest that the consumption estimates based on summation of different fish types are likely upwardly biased by approximately 30%.

The 2001 Chesapeake Bay occupational and recreational fishers survey is of limited usefulness to the Pepco Anacostia River risk assessment for several reasons: fish consumption represents all sources of fish, not just self-caught, the predominantly White study population differs from Anacostia River anglers (largely non-White), and marine fish that would not typically be present represent a large portion of the diet (e.g., flounder and sea trout).

Chesapeake Bay Angler Survey

In 2004, researchers from Virginia Polytechnic Institute and State University, under contract to the Chesapeake Bay Program, conducted on-site angler interviews in three regions of concern: 1) Baltimore, Maryland area, 2) Washington, DC area, and 3) Tidewater, Virginia area (Gibson and McClafferty, 2005). The purpose of the study was to characterize anglers' demographic characteristics and consumption behaviors, as well as their knowledge of consumption advisories. The interviews were conducted over 8 weeks in June–August at nine predetermined fishing sites in each study area. Of the nine intercept sites in the Washington, DC study area, seven were located on the Potomac River, one on the Anacostia River (Anacostia Park South[1]), and one on the bay south of the confluence of the two rivers. The individual site sampling frequencies were weighted to sample the sites where anglers were expected more frequently, based on consultations with fishery managers and visual observations of survey staff (Gibson and McClafferty, 2005). Interview teams visited assigned sites for 8-hour shifts (morning shift of 6 am to 2 pm and afternoon shift of 12 noon to 8 pm).

A total of 247 interviews were conducted in the DC area. The study attempted to interview each angler only once, although the authors report that 9% of the 247 intercepts were with anglers that had been interviewed earlier in the summer. Most anglers (91%) were male, and the average age was 45. Most (84%) had obtained at least a high school education. Half of the anglers were African-American, 33% were White, 10% were Hispanic, and 6% were Asian. About 40% reported annual household incomes above $80,000, about 30% reported annual household incomes of $40,000 to $80,000, and 30% reported less than $40,000. About 9% reported annual household incomes of less than $20,000.

[1] Gibson's 2005 Master's thesis: *Fish Consumption Advisories in Tributaries to the Chesapeake Bay: Improving the Communication of Risk to Washington, DC Anglers*, provided additional information on the 2004 survey. In the thesis, the Anacostia South Park survey site was depicted on a map on the east side of the river adjacent to the Pennsylvania Ave. Bridge (Sousa Bridge). This location is approximately 1.8 miles downriver from the Pepco Site. Anacostia South Park (site 9) was visited six times during the 8-week survey period. Two of the visits were conducted on weekend days, while the other four were on weekdays. Five of the six visits took place during the afternoon shift, and one visit took place during the morning shift. A total of 13% (about 30 interviews) of all DC area interviews were conducted at the Anacostia South Park site, ranking fourth out of the nine DC area sites.

About 37% reported eating some of their catch, and 63% reported practicing catch and release only. Of those who reported consuming their catch, 75% reported avoiding certain species. About half of anglers who reported not consuming their catch said they sometimes gave away their catch. When consuming anglers were asked to name up to four species consumed and consumption frequency, catfish (listed as a “do not eat” species) was the most popular species, followed by stripers and largemouth bass. For the other two “do not eat” listed species (carp and eel), only three anglers reported consuming carp, and none reported consuming eel.

Most anglers reported fishing and eating their catch in the warmer months (April–September). During these warmer months, 53% of consuming anglers reported a consumption rate of 1 to 3 times per month, and 20% reported a consumption rate of 1 to 2 times per week. On average throughout the year, anglers ate their catch less than once per month (44%) or between one and three times per month (29%). Only 2% reported eating self-caught fish more than twice a week throughout the year. Asian and Hispanic anglers were more likely to consume their fish than anglers of other ethnicities, and were also more likely to provide their catch to other family members. The majority (about 60%) reported removing the skin and trimming the fat, and most (78%) reported eating 8 ounces or less for a typical meal. Of the 247 DC area anglers interviewed, only 6 reported eating crabs. When asked about reasons for fishing, over 90% of the anglers reported being outdoors or relaxing as very important. About 20% reported getting fresh fish for a family meal as a very important reason. About 56% of the interviewed anglers reported awareness of the consumption advisories.

The 2004 Chesapeake Bay Angler Survey includes consumption and behavior data for anglers on the Potomac River and Anacostia River that may be useful for the risk assessment. The survey questions asked about consumption and sharing habits related to “self-caught” fish from the Washington, DC area, although not necessarily specific to the Anacostia River. Population statistics were not generated, and sampling weights were not provided. Thus, there is uncertainty as to the representativeness of the interview data to the larger population of Anacostia River anglers and consuming anglers. In addition, the survey was administered over an 8-week period of high fishing activity, and anglers were asked to recall year-round practices. There is uncertainty in using one-time recall data to estimate long-term consumption rates (USEPA, 2011). Recall survey methods tend to bias consumption rates high, especially for more avid anglers and with longer recall periods (USEPA, 1998; Connelly and Brown, 1995; Fisher et al., 1991). “Recall bias” may be further amplified when the respondent is interviewed at the height of the fishing season, and responses extrapolated to cold weather months when fishing activity is much lower. This bias will lead to overestimating annual consumption rates (USEPA, 2011).

Anacostia River Angler Survey

OpinionWorks, under contract to the Anacostia Riverkeeper and with multi-agency support, conducted a study to assess the characteristics, practices, and attitudes of Anacostia River anglers (OpinionWorks, 2012). On-site interviews were conducted on various days of the week and hours of the day from early morning to evening, over 5 weeks in August and September 2011 at 10 fishing sites between Bladensburg, Maryland and the mouth of the Anacostia River near Hains Point in the District of Columbia. Interviews were administered predominantly in English (85%), with the remainder in Spanish (14%) and Vietnamese (1%). Information was gathered on fishing practices, fish consumption and sharing, and awareness of health risks. Of the 111 anglers interviewed, 67% were African American, 18% were Hispanic, 8% were Asian, and 6% were White. About 62% had a high school education, and 25% never completed high school. About 63% of the interviewed anglers reported fishing at least once a week during the warm weather months, and 18% reported fishing daily during warm weather months. When shown a photo sheet of fish species in the river, catfish was reported as caught most often (65% of anglers), followed by brown bullhead (33% of anglers) and sunfish (20% of anglers). About 75% of anglers reported eating or sharing some or all of their catch, and about 25% practice catch and release only. About one third (35%) reported eating or sharing their catch once per week, and 7% reported eating fish every day. Nearly half (46%) reported sharing self-caught fish outside of their family. The goal of this study was to understand fishing, consumption, and sharing practices of anglers; however, the study was not designed and did not collect the data necessary to calculate long-term fish consumption rates and was therefore not used in developing fish consumption rates for this BHHRA.

National Park Service (NPS) Survey of Potomac and Anacostia River Anglers

The Interim report *Subsistence Fishing on the Potomac and Anacostia Rivers* (NPS, 2016) summarizes a survey of anglers who fish from NPS-managed land in the DC area. The study was initiated in 2014 with identification of popular fishing spots along 47 miles of riverfront along the Potomac and Anacostia Rivers, followed by in-field angler interviews in late spring through fall of 2015. The purpose of the study was to determine the extent of non-recreational fishing, and the social, cultural, and community context of fishing in the two rivers. By design, the study targeted anglers who appeared to be harvesting for consumption and/or sharing. The sampling design is based on an availability sample versus a random sample, which limits extrapolation of study findings to the broader population of anglers fishing in the study area (NPS, 2016). The authors state that four basic questions underlie the study: Why are people fishing on the rivers and eating their catch; what motivates them to do this and what does it mean to them? Who are the anglers and fisher women doing the fishing and what are they catching? How and what kind of sharing is going on? And what is the extent of food insecurity among people who are fishing?

As stated in the NPS report:

> By using anthropological methodology and techniques, this study aims to provide a deeper understanding of the cultural communities represented by anglers, and their relation to the land and river resources. The resulting ethnographic resource study will provide (l) an ethnohistorical overview of fishing on the Potomac and Anacostia Rivers, (2) ethnographic data about contemporary anglers, and (3) an understanding about the cultural relevance of park resources to people and groups....

As such, the study focuses on the social, economic, and cultural reasons for fishing in the national park, and was not designed to collect the data necessary to estimate fish consumption rates for use in a risk assessment. Documentation of fish harvests, and plans for consumption and sharing captured through diaries or repeated intercepts with anglers, are more reliable methods of collecting data for deriving reliable estimates of long-term fish consumption rates. The initial study results are based on 35 angler interviews, the majority of which (31 of 35) were with anglers fishing on the Potomac River; only 4 of the interviewed anglers were fishing on the Anacostia River.[2] The documentation of the NPS study is limited, and the survey was designed with quantification of angler fishing and harvest as an objective. Further, the study represents the responses of a small sample size; a total of 35 anglers were interviewed, of which only 4 were intercepted on the Anacostia River. Therefore, this study was not used in developing fish consumption rates for this BHHRA.

<u>Selected Fish Consumption Rates</u>

The Chesapeake Bay angler survey was selected as the most appropriate study for use in deriving fish consumption rates for the Benning Road BHHRA. This study was selected because it followed general survey design methods, recorded 247 interviews over an 8-week period, included the Anacostia River, identified species preferences, and presented consumption frequency ranges. While the Chesapeake Bay angler survey was not conducted with the intention of collecting data for use in a BHHRA, the available data are sufficient to develop consumption estimates for DC area anglers. Since the survey was conducted during the warm weather period when fishing activity tends to be highest, angler responses regarding fishing and consuming frequency are likely to be biased upward (recall bias). As previously noted, this bias tends to result in overestimating annual consumption rates (USEPA, 2011). The angler surveys by OpinionWorks (2012) and NPS (2016) provide generally qualitative information on anglers, motivations for fishing, and general consuming and sharing practices; this information has also been considered in the development of the fish consumption exposure parameters.

For the RME scenario, a fish consumption rate of 20 grams/day was used for the adult angler. This rate equates to approximately 32 half-pound meals per year of self-caught fish, and was derived based on

[2] The authors report that a second phase of interviews is planned, with a final sample size goal of 100 interviews (NPS, 2016).

angler responses on frequency of eating their catch. The rate assumes one-half pound of self-caught fish meal per week during the six warmer months of the year (April through September) and one meal per month during the six cooler months of the year (October through March). For the CTE scenario, a fish consumption rate that is half of the RME rate (10 grams/day) was used for the adult angler. The assumption that a typical fish meal consists of a half-pound of fish is conservative, as nearly 80% of anglers reported consuming 8 ounces or less (Gibson and McClafferty, 2005).

Consumption rates for the older child/teen and young child were based on the assumption that intakes are approximately two-thirds and one-third, respectively, that of the adult. This assumption is based on the ratios of mean child-to-adult fish ingestion rates for fish consumption (USEPA, 2011). The derivation of the recreational angler consumption rates is presented in **Table C-1**. The RME and CTE fish consumption rates used in the BHHRA are shown below in units of grams per day and fish meals per year, assuming typical meal sizes of 8 ounces (227 grams) for the adult, 6 ounces (170 grams) for the older child, and 4 ounces (113 grams) for the young child.

	Fish Consumption Rates Recreational Angler			
	RME		CTE	
Angler Age Group[a]	**g/day**	**meals/year**	**g/day**	**meals/year**
Adult	20	32	10	16
Older child/teen	13	28	7	15
Young child	7	23	3	10

[a] Age groups: adult = 19+ yrs; older child/teen = 7 to <19 yrs; young child = 1 to <7 yrs.

Based on the survey results presented in Gibson and McClafferty (2005), some anglers supplement a sizeable fraction of their diet with river fish. The BHHRA includes an analysis of a high-end consuming angler who fishes year-round and consumes two fish meals per week of Anacostia River fish, as indicated below.

	Fish Consumption Rates High-end Consuming Angler	
	RME	
Angler Age Group[a]	**g/day**	**meals/year**
Adult	65	104
Older child/teen	43	69
Young child	21	33

[a] Age groups: adult = 19+ yrs; older child/teen = 7 to <19 yrs; young child = 1 to <7 yrs.

Because there is a current fish consumption advisory, it is possible that fish consumption rates would increase in the future if the advisory is lifted. Additional improvements in the river could also lead to increased fish consumption in the future. Section 7.3.2 of the main text of this BHHRA discusses uncertainties in fish consumption rates and potential future changes in the advisory or river conditions.

2.2 Fraction Ingested

The Risk Assessment Guidance for Superfund (RAGS) Part A includes the term “fraction ingested” (FI), which is defined as the “fraction ingested from contaminated source (unitless)” (USEPA, 1989a). Anglers fish at multiple locations and likely obtain catch from several locations throughout the Anacostia River and the broader DC area, including the Potomac River and upper Chesapeake Bay. The use of a FI of less than 1 translates to assuming that a portion of the angler’s self-caught fish diet comes from locations other than the Anacostia River in the vicinity of the Site. The size of the Pepco Waterside Investigation Area (approximately one-half mile of shoreline) relative to the length of the Anacostia River (approximately 8.4 miles from Bladensburg to the confluence with the Potomac River) is less than 6 percent. In addition, fish move throughout the river, with home ranges for some species of up to several miles (e.g., catfish, carp, striped bass). For the RME scenario, it was assumed that half of the fish consumed by the angler comes from the Anacostia River in the vicinity of the Site (FI = 0.5). For the CTE scenario, a FI of 0.25 was used to account for anglers who catch and eat fish from throughout the greater DC area. An FI was not applied to the high-end consuming angler scenario.

3 Soil and Fringe Sediment Ingestion Rates

While a number of studies on incidental ingestion of soil as a result of hand-to-mouth behaviors have been conducted, as summarized in USEPA guidance (2011), similar data for sediment are lacking. Incidental ingestion of sediment is generally expected to be limited since submerged sediments tend to be washed off of the exposed skin (USEPA, 2004). Since empirical, site-specific measurements of sediment ingestion are not feasible, the development of appropriate incidental sediment ingestion rates for the BHHRA entailed the use of soil ingestion rates published in USEPA guidance (USEPA, 2011, 2014).

The USEPA’s default upper-bound residential soil ingestion rates are 200 mg/day for young children (1 to <7 years of age) and 100 mg/day for adults (USEPA, 2014). These soil ingestion rates are intended to capture exposure to outdoor soil and household dust of outdoor soil origin (USEPA, 2011). The rate for the young child is based on two soil ingestion studies (Özkaynak et al., 2010; Stanek and Calabrese, 1995). The rate for the adult is based on the 1991 version of the standard default exposure factors, because USEPA (2011) does not provide upper-bound values. USEPA has adopted the upper 95th percentile soil ingestion rate from Stanek et al. (1997) as the default construction worker ingestion rate of 330 mg/day (USEPA, 2002).

Because of uncertainty in the fraction of total daily intake that is composed of fringe surface sediment versus soil, and Site versus non-Site, and also to provide a conservative, upper-bound estimate, the default values for incidental soil ingestion (USEPA, 2002, 2014) were used as the basis of the soil and fringe surface sediment ingestion rates for the BHHRA. The rates were adjusted for recreational receptors to account for the fraction of the total daily intake derived from river fringe surface sediment or Site soil relative to the fraction derived from the backyard, household dust, and other non-Site sources. It was conservatively assumed that on the days when the recreational receptor visits the River or Site, approximately 50% of the total daily intake would be derived from river fringe surface sediment or Site soil, and 50% would be from backyards, household dust, and other non-Site-related locations. The same relative source apportionment was applied to the CTE rates, which are assumed to be 50% of RME rates. For non-recreational receptors, it was assumed that 100% of the daily intake rate comes from river fringe surface sediment or Site soil. The selected fringe surface sediment and soil incidental ingestion rates for Waterside and Landside receptors are summarized below.

Waterside Receptors	USEPA Default Total Daily Soil Intake Rate		Assumed River Fringe Surface Sediment Ingestion Rate	
	RME	CTE	RME	CTE
	mg/day	mg/day	mg/day	mg/day
Angler, Swimmer, Wader (adult)	100	50	50[a]	25[a]
Angler, Swimmer, Wader (older child/teen)	100	50	50[a]	25[a]
Angler, Swimmer, Wader (young child)	200	100	100[a]	50[a]
Shoreline Worker (adult)	100	50	100	50

Notes:
[a] It is assumed that 50% of the receptor's total daily intake rate is associated with backyard soils, household dust, and other off-Site sources, which are not included in the BHHRA, and that 50% is river fringe surface sediment.

Landside Receptors	USEPA Default Total Daily Soil Intake Rate		Assumed On-Site Soil Ingestion Rate	
	RME	CTE	RME	CTE
	mg/day	mg/day	mg/day	mg/day
Construction Worker (adult)	330	330	330	330
Outdoor Industrial Worker (adult)	100	50	100	50
Recreational Visitor (older child/teen)	100	50	50[a]	25[a]

Notes:
[a] It is assumed that 50% of the receptor's total daily intake rate is associated with backyard soils, household dust, and other off-Site sources, which are not included in the BHHRA, and that 50% is Site soil.

4 Surface Water Ingestion Rate

While a number of studies on drinking water ingestion rates have been conducted, as summarized in USEPA guidance (2011), similar data for incidental surface water ingestion are generally lacking, especially for activities such as wading or boating. However, USEPA (2011) provides incidental water ingestion rates during swimming. The ingestion rates are based on a pilot study in which 53 participants (12 adults and 41 children) swam for 45 minutes in a community outdoor swimming pool treated with chloroisocyanate. Cyanuric acid in the urine of each participant was used as an indicator of pool water ingestion exposure (see the table below). The upper percentile rates are based on the 97th percentile for children and the maximum value for adults. While the use of these values from a small-scale pilot study may not be appropriate, the upper-bound values reported in USEPA (2011) were used for the RME scenario, and the mean values were used for the CTE scenario. As the CTE scenario is meant to represent average conditions, the mean values are more appropriate than the upper-bound, which reflect greater than 95th percentiles.

Age	Mean (mL/hour)	Upper Percentile (mL/hour)
Children	49	120
Adults	21	71

Estimates of incidental water ingestion that occurs during water recreational activities other than swimming are not provided in USEPA guidance. However, a study of incidental water ingestion during limited-contact recreation was identified in the peer reviewed literature (Dorevitch et al., 2011). Self-reported estimates of incidental water ingestion were obtained from approximately 2,700 people (6 years of age or older) who were canoeing, kayaking, and fishing in Chicago area surface waters. A second study evaluated 662 people in swimming pools involved in full contact (i.e., swimming) and limited contact recreational activities, such as canoeing, kayaking (including capsizing), simulated fishing, and wading/splashing. The surface water study was an observational design study with no time limit on the duration of the activity. The swimming pool study was a controlled exposure design of 60 minutes and a subsequent urine analysis 24 hours later to measure levels of cyanuric acid (a tracer of swimming pool water). Of the surface water participants, less than 2% reported swallowing a teaspoon or more, and less than 0.5% reported swallowing a mouthful or more (Dorevitch et al., 2011).

The authors report the mean and upper confidence limit for incidental surface water ingestion rates of 3 to 4 mL per event and 10 to 15 mL per event, respectively, for limited-contact recreational exposures to surface water (e.g., canoeing, kayaking, fishing) (Dorevitch et al., 2011). The midpoint of the upper confidence limit rate of 13 mL per event and the mean rate of 4 mL per event was used for the RME and CTE incidental surface water ingestion rates, respectively, for the non-swimming exposure scenarios (angler, wader, worker) and all age groups.

5 Body Surface Area Exposed

Recreational visitors, as well as industrial workers and construction workers, may come into contact with soil while on-Site. Recreational receptors may come into contact with fringe surface sediment and surface water while wading in shallow areas of the River to play or fish, or occasionally swimming in the River. The shoreline worker receptor may contact fringe surface sediment and surface water while performing maintenance or other work-related activities along the shoreline. For the evaluation of potential risk from direct contact with fringe surface sediment during swimming, wading, and angling, it is assumed that some fringe surface sediment remains adhered to the skin surface after the event.

Tables C-2 through **C-6** present the calculation of the exposed body surface areas. The same exposed skin surface areas were used in the RME and CTE scenarios.

<u>Worker Receptors</u>

For the adult outdoor industrial worker, construction worker, and shoreline worker, the head, hands, and forearms are assumed to remain in contact with soil (industrial worker, construction worker) or fringe surface sediment and surface water (shoreline worker). USEPA derived a default value of 3,527 cm^2 using the average of males and females for this body surface area (USEPA, 2014). The default value is used in this BHHRA.

<u>Recreational Visitor</u>

The older child/teen recreational visitor may come into contact with surface soil on-Site. It is assumed that the head, hands, forearms, and lower legs are potentially exposed. Based on these body parts, a mean surface area of 3,950 cm^2 was calculated in **Table C-2** for males and females age 7 to <19.

<u>Swimmer Receptor</u>

For the swimmer receptor, the entire body surface area is assumed to be exposed to surface water. The body surface areas for the swimmer, calculated using the average of males and females, are as follows (USEPA, 2011, 2014):

- Adult swimmer = 20,900 cm^2
- Older child/teen swimmer = 14,825 cm^2
- Young child swimmer = 7,500 cm^2

Table C-3 presents the calculation of the total body surface area for the young child and older child/teen swimmer. The total body surface area for the adult swimmer was taken from USEPA (2014).

For the swimmer's exposure to fringe surface sediment, not all of the body surface area is assumed to remain in contact with fringe surface sediment. Sediment from deeper water is expected to wash off of the body upon exiting the water (USEPA, 2004). For the adult and older child/teen swimmer, the lower legs and feet are assumed to remain in contact with fringe surface sediment. For the young child swimmer, more of the body surface is assumed to remain in contact with fringe surface sediment, including the hands, forearms, lower legs, and feet.

Thus, using the average of males and females and weighted averages by year for each child body part, the body surface areas exposed to fringe surface sediment are as follows for the swimmer (USEPA, 2011):

- Adult swimmer = 3,800 cm^2 (**Table C-4**)
- Older child/teen swimmer = 2,710 cm^2 (**Table C-5**)
- Young child swimmer = 2,057 cm^2 (**Table C-6**)

Wader and Angler Receptors

For the water and angler receptor's exposure to fringe surface sediment and surface water, the same body surface areas exposed to sediment for the swimmer are used.

6 Soil and Sediment Adherence Factors

To account for differences in adherence for different parts of the body, an area-weighted adherence factor is calculated using body part-specific adherence levels. For each receptor, the skin surface area of each exposed body part is multiplied by its body part-specific adherence factor to yield a total mass adhered to that body part. The total masses are then summed for all exposed body parts, and then divided by the total body surface area exposed to derive the area-weighted adherence factor.[3]

Soil

USEPA (2014) provides a default soil adherence factors for outdoor workers of 0.12 mg/m^2. USEPA (2002) provides a default soil adherence factor for construction workers of 0.3 mg/m^2. These defaults are used in this BHHRA. For the older child/teen recreational visitor to the Landside area, a soil adherence factor of 0.01 mg/m^2 was calculated based on soil loading rates for soccer players (see **Table C-2**).

[3] An implicit assumption in the dermal dose model is that exposure (and absorption of contaminants by the skin) occurs for each event in which soil/sediment contacts the exposed body surface area without regard to the duration of the exposure event. This is a conservative assumption, as desorption of contaminants from soil/sediment is a slow diffusive process driven by the magnitude of the concentration gradient between internal regions where contaminants are sequestered and the surface where a low concentration is maintained (Shor et al., 2004). Further, not all of the soil contaminant may be absorbed for various reasons, including matrix effects, volatilization, skin loading, washing, or abrasion of soil from skin, etc. (Spalt et al., 2009).

Fringe Surface Sediment

USEPA (2004,) recommends sediment adherence data for children from several studies, including children playing indoors, at daycare, in dry soil, in wet soil, in mud, on tidal flats, during gardening, and while playing soccer. The activity and conditions that most closely align with receptor activities at the River is children playing in wet soil. Therefore, the fringe surface sediment adherence factors for the older child/teen and young child were based on the geometric mean surface area weighted soil adherence data for children playing in wet soil (USEPA, 2004, Exhibit C-2). The fringe surface sediment adherence factor is 0.25 mg/m^2 for the older child/teen (see **Table C-5**) and 0.28 mg/m^2 for the young child (see **Table C-6**).

USEPA (2011) provides sediment adherence data for adults from several studies, including one of adults gathering reeds on tidal flats (‘reed gatherer’). Therefore, the fringe surface sediment adherence factors for adults were based on data for the reed gatherer (USEPA, 2011, Table 7-20). The calculated fringe surface sediment adherence factor for recreational adults and the shoreline worker is 0.3 mg/m^2 (See **Table C-4**).

7 Exposure Frequency and Exposure Time

Exposure frequency is the number of days per year that a receptor engages in a particular activity that could result in exposure. Exposure time is the duration of the event that brings the receptor into contact with the environmental medium.

Landside Exposure Pathways

An exposure frequency of 40 days per year is assumed for the construction worker, assuming 5 days per week for a period of 2 months (8 weeks) under the RME scenario. Under the CTE scenario, an exposure frequency of 20 days per year is assumed, assuming 5 days per week for one month (4 weeks).

The USEPA (2014) default for an outdoor worker of 225 days per year is used for the industrial worker under the RME scenario. Under the CTE scenario, an exposure frequency of 219 days per year is assumed based on the central tendency estimate for industrial workers in USEPA (2004).

The older child/teen recreational visitor is assumed to visit the site one day per week for May, September, and October, and two days per week for the summer, June through August (for a total of 39 days per year) under the RME scenario, and one day every other week from May to October (13 days per year) under the CTE scenario.

Waterside Exposure Pathways

Exposure frequencies and exposure times for recreational scenarios involving direct contact with fringe surface sediment and surface water were based on site-specific factors, including:

- Nature of the activity (e.g., swimming vs. wading)
- Characteristics of the area, including access and nearby land use
- Climate factors such as temperature and precipitation (e.g., sediment contact is curtailed during cold weather months when the sediment is frozen or snow covered)

Exposure to fringe surface sediment and surface water is expected to occur predominantly in the warmer months of the year, when people are more likely to visit the River and more of the skin surface area is exposed. It is assumed that swimming occurs during the three summer months (June, July, and August), when monthly average water temperatures are comfortable for swimming, typically above 70 degrees Fahrenheit (USGS, 2015). However, given the absence of designated swimming locations on the Anacostia, as well as aesthetic and safety considerations, swimming is expected to be an infrequent event now and in the future. It is assumed that wading may occur during the months of May, June, July, August, and September, when monthly average water temperatures are above 60 to 65 degrees Fahrenheit (USGS, 2015). While some anglers may fish year-round, most fishing takes place during the months of April through September (Gibson and McClafferty, 2005). It is assumed that the shoreline worker may contact shoreline fringe surface sediment and surface water once a week when the ground is not frozen or snow covered, or when such activity is not precluded by inclement weather.

Based on consideration of climate, characteristics of the Study Area, and the nature of the activity, the fringe surface sediment and surface water exposure frequencies for each receptor scenario are summarized below. The exposure frequency is assumed to be once or twice a week during the months of the year when the activity is assumed to take place. For the swimmer and wader receptors, exposure frequencies for the older child/teen are higher than for the young child and adult, as older children are more likely to engage in activities that may bring them into direct contact with river fringe surface sediment and surface water.

Receptor Population	Age Group[a]	Fringe Surface Sediment Exposure Frequency (days/year)		Surface Water Exposure Frequency (days/year)	
		RME	CTE	RME	CTE
Angler	Adult	26	13	26	13
	Older child/teen	26	13	26	13
	Young child	26	13	26	13
Swimmer	Adult	13	6	13	6
	Older child/teen	26	13	26	13
	Young child	13	6	13	6
Wader	Adult	35	17	35	17
	Older child/teen	43	22	43	22
	Young child	35	17	35	17
Worker	Adult	50	25	50	25

[a] Age groups: adult = 19+ yrs; older child/teen = 7 to <19 yrs; young child = 1 to <7 yrs.

The surface water and sediment exposure frequencies presented above were developed taking into consideration the existing parks, walking trails, boat docks, and fishing activity within the Waterside Investigation Area, as well as potential improvements in these resources. However, it is possible that River use could increase at a rate higher than assumed. Section 7.3 of the main text of this BHHRA discusses uncertainties associated with the assumed exposure frequencies.

The surface water exposure times for each receptor scenario were also selected taking into consideration the characteristics of the Study Area and the nature of the activity. As previously noted, exposure time is not used in the calculation of intake from fringe surface sediment dermal contact. The surface water exposure times are summarized in the table below.

Receptor Population	Age Group[a]	Surface Water Exposure Time (hour/day)	
		RME	CTE
Angler	Adult	1	0.5
	Older child/teen	1	0.5
	Young child	1	0.5
Swimmer	Adult	0.5	0.25
	Older child/teen	0.5	0.25
	Young child	0.5	0.25
Wader	Adult	1	0.5
	Older child/teen	1	0.5
	Young child	1	0.5
Worker	Adult	2	1

[a] Age groups: adult = 19+ yrs; older child/teen = 7 to <19 yrs; young child = 1 to <7 yrs.

8 Exposure Duration

Exposure duration is the estimate of the total time of exposure (in years) that a receptor engages in a particular activity that could result in exposure.

The older child/teen recreational visitor, angler, wader, and swimmer receptors are assumed to be potentially exposed at the Site for 12 years (from age 7 to <19 years) under the RME scenario. Under the CTE scenario, these receptors are assumed to be potentially exposed at the Site for half of that time, 6 years.

The outdoor industrial worker and the shoreline worker are assumed to be exposed at the Site for 25 years under the RME scenario (USEPA, 2014). Under the CTE scenario, workers are assumed to be potentially exposed at the Site for 6.6 years, which is the median tenure for workers at the same job (USEPA, 2011).

Construction activities are assumed to occur over a 1-year period under both the RME and CTE scenarios.

Anglers, swimmers, and waders are assumed to be nearby residents, and as such, residential exposure durations are used to evaluate adults and young children. To estimate residential exposure duration, both the total occupancy period for individuals in the target population and the likelihood that at the end of each occupancy period the individual moves out of the area must be known. Estimating exposure duration (i.e., residence time) is complicated by a number of factors, including data availability and the statistical treatment of the data. Few studies are available with which to estimate population mobility within a targeted area, and the use of county data requires a detailed analysis that accounts for age at onset, mortality, and county-to-county mobility.

In USEPA’s 2014 recommended default exposure factors, USEPA identifies 26 years as the upper bound default for residential exposure duration (USEPA, 2014). Therefore, under the RME scenario, a 26-year exposure duration was selected for the recreational receptors (6 years during childhood and 20 years during adulthood), assuming that these individuals live within the vicinity of the Site. Under the CTE scenario, an exposure duration of 12 years (2 years during childhood and 10 during adulthood) was selected based on the mean residential occupancy period (USEPA, 2011).

9 Body Weight

In accordance with USEPA (1989a), the value for body weight is the average body weight over the exposure period. There are extensive data on human body weight, much of which has been compiled in the Exposure Factors Handbook (EFH) (USEPA, 2011). The EFH provides recommended body weights for adults and children, which are based on data derived from the National Health and Nutrition Examination Survey (NHANES) for the years 1999 through 2006. The NHANES study is a nationally representative sample of the U.S. population, with participants selected using a probability-based sampling design, and has been continuously conducted since 1999. Since the 2011 update to EFH, more recent anthropometric reference data for U.S. children and adults collected under NHANES for the years 2007 through 2010 have been published by the National Center for Health Statistics (Fryar et al., 2012).[4] Not only are these data more recent, they are provided for each year of a child’s age from birth to 19 years, unlike the body weight data in EFH, which are weighted averages for multi-year age groups (e.g., 3 to <6 yrs, 6 to <11 yrs). The use of single-year body weight data rather than averages for multiple years of age allows for calculation of age group-specific body weights on a more refined basis. Therefore, the NHANES 2007–2010 body weight data (Fryar et al., 2012) were used to estimate body weight for the young child and older child. Consistent with the approach in EFH, the average of the body weights for males and females for each year of age was used to calculate the average receptor body weight over the exposure period.

[4] The NHANES 2007–2010 sample included participants of all ages. Those aged 60 and over, Hispanics, Blacks, and those with low incomes were oversampled to improve the precision of the statistical estimates for these groups (Fryar et al., 2012).

National values are typically used, unless a specific population that differs from the nation as a whole is targeted. Since the receptor population in the vicinity of the Anacostia River is not expected to differ from the rest of the United States, national average body weight values were used.

Body weights for children and teenagers were calculated as shown in **Table C-7.** The selected body weight for the young child receptor is 17 kilograms (kg) for both the RME and CTE scenarios, and the selected body weight for the older child/teen receptor is 53 kg for both the RME and CTE scenarios. The selected body weight for adult receptors under both the RME and CTE scenarios is 80 kg, which is the national average for male and female adults (USEPA, 2011, 2014).

Table C-1
Calculation of Fish Consumption Rates for Recreational Angler Receptor (a)
Benning Road Facility RI/FS Project
3400 Benning Rd, N.E., Washington DC 20019

Reasonable Maximum Exposure (RME)

Time period	**Apr-Sept**	
number months	6	
weeks/month	4.3	
total weeks	26	
meals/week	1.0	
total meals (Apr-Sept)	*26*	
Time period	**Oct-Mar**	
number months	6	
meals/month	1.0	
total meals (Oct-Mar)	*6*	
Total year-round meals	***32***	
Meal size (grams)	***227***	(b)
Grams/day (annualized)	***20***	(c)

RME Adult Angler (g/day)	20	
RME Older Child/Teen Angler (g/day)	13	(e)
RME Young Child (g/day)	7	(e)

Central Tendency Exposure (CTE)

Time period	**Apr-Sept**	
number months	6	
weeks/month	4.3	
total weeks	26	
meals/week	0.5	
total meals (Apr-Sept)	*13*	
Time period	**Oct-Mar**	
number months	6	
meals/month	0.5	
total meals (Oct-Mar)	*3*	
Total year-round meals	***16***	
Meal size (grams)	***227***	(b)
Grams/day (annualized)	***10***	(d)

CTE Adult Angler (g/day)	10	
CTE Older Child/Teen Angler (g/day)	7	(e)
CTE Young Child (g/day)	3	(e)

Notes:
(a) Rates are based on responses of Washington DC area anglers that participated in 2004 Chesapeake Bay Angler Survey (Gibson & McClafferty, 2005). During warmer weather months (Apr-Sept), 53% of consuming anglers reported eating their catch 1 to 3 times/month, and 20% reported eating their catch 1-2 times/week. On average throughout the year, anglers ate their catch less than once per month (44%) or between one and three times per month (29%). Additional support obtained from Anacostia River Angler Survey (OpinionWorks, 2012).
(b) Meal size assumed to be 8 ounces (227 grams). Most anglers (78%) reported eating 8 ounces or less at a meal. In addition, an 8-ounce serving size is used to set fish consumption advisories.
(c) RME adult rate assumes one meal/week during 6 warmer months of the year (Apr-Sept) and 1 meal/month during 6 cooler months of the year (Oct-Mar) for a total of 32 meals/year (expressed in grams/day averaged over 365 days/year). RME rate equates to catching ~53 pounds of whole fish per year assuming ~30% is edible (USEPA, 1989).
(d) CTE adult rate assumes one meal every other week during 6 warmer months of the year (Apr-Sept) and 1 meal every other month during 6 cooler months of the year (Oct-Mar) for a total of 16 meals/year (expressed in grams/day averaged over 365 days). CTE rate equates to catching ~27 pounds of whole fish per year assuming ~30% is edible (USEPA, 1989).
(e) Consumption rates for older child and young child are assumed to be two thirds and one third of adult rate, respectively (USEPA, 2011). Rates are rounded to integers.

Attachment D

Derivation of Cooking Loss Factors

Attachment D
Derivation of Cooking Loss Factors

Loss of hydrophobic chemicals of potential concern (COPCs) upon cooking is a recognized phenomenon and can have a significant effect on the calculated COPC exposure dose from tissue consumption by humans. Numerous published studies have evaluated contaminant loss from fish tissue as a result of cooking, many of which have been summarized in scientific literature reviews (Sherer and Price, 1993; Wilson et al., 1998; Zabik and Zabik, 1999), as well as agency guidance on assessing contaminants in fish consumption advisories (USEPA, 2000).

The goals of the evaluation are as follows:

- Perform an updated literature review to include more recent studies on cooking loss in fish, focusing on lipophilic organic chemicals
- Evaluate relevant data on a consistent basis that accounts for changes in tissue mass as a result of cooking processes; this is most commonly done by considering the mass of COPC in the edible tissue before and after cooking
- Identify studies with sufficient data for quantitative analysis to determine the range and midpoint on a chemical- and cooking method-specific basis
- Evaluate the importance of other specific factors influencing the extent of cooking losses, such as species, skin-on versus skin-off preparation, lipid content, and cooking duration and temperature
- Identify cooking loss factors for use in the baseline human health risk assessment (BHHRA) for the Pepco Benning Road Facility for both reasonable maximum exposure (RME) and central tendency exposure (CTE) scenarios

A total of 34 relevant studies were identified, as summarized in **Table D-1**. Of the 34 relevant studies identified, 29 address polychlorinated biphenyls (PCBs) as mixtures or Aroclors, two address coplanar or so-called “dioxin-like” PCB congeners, 13 address one or more dichlorodiphenyltrichloroethane and its derivatives (DDx), and nine address one or more dioxin and furan congeners. The studies address a variety of fish species, including striped bass, carp, trout, bass, catfish, perch, flounder, salmon, walleye, and bluefish. A variety of cooking methods are represented, including baking/roasting, broiling, grilling, boiling, poaching, pan frying, deep frying, microwaving, and smoking. Four of the 34 studies are review articles; where possible, the original studies and data were used in this evaluation. The full list of studies reviewed is presented in the references. A number of other studies related to cooking loss in other foodstuffs, such as beef, and other contaminants, such as inorganics, were also identified. However, because this analysis focuses on lipophilic organic compounds and fish, they are not included.

The pool of studies was narrowed to 17 that used a relevant and appropriate experimental method and presented changes in raw and cooked fish tissue COPC levels on a mass basis or provided sufficient data for calculating mass loss of COPCs (see **Table D-2**). Comparison of concentrations in raw and cooked fish alone neglects the change in tissue mass that occurs, which is often significant. Therefore, this evaluation addresses the change in COPC levels on a consistent, mass basis. The percentage of COPC mass lost during cooking was calculated as follows:

$$\frac{\text{COPC mass in uncooked fillet} - \text{COPC mass in cooked fillet}}{\text{COPC mass in uncooked fillet}} \times 100$$

For studies that did not report loss on this basis, but provided the necessary data (e.g., pre- and post-cooking tissue concentrations and weights, or weight loss factor), it was possible to calculate loss on a mass basis from the data provided.

The mass-based method of quantifying cooking loss is consistent with numerous studies, including those of Zabik and colleagues (1979, 1995a,b,c, 1996), Stachiw et al. (1988), Sherer and Price (1993), Moya et al. (1998), Wilson et al. (1998), and Wang and Harrad (2000). It is also the approach used in the PCB cooking loss analysis for the Hudson River HHRA. For one study (Smith et al. 1973), it was necessary to calculate mass loss differently due to the type of data provided. For Smith et al. (1973), mass loss was calculated following the method described in Sherer and Price (1993), as follows:

$$\frac{\text{Mass of COPC in drippings}}{\text{COPC mass in cooked fillet} + \text{COPC mass in drippings}} \times 100$$

The mass of COPC in drippings and cooked fillet was calculated as:

$$M_{COPC} = C_{COPC} \times F \times M_r$$

Where:

M_{COPC} = Mass of COPC in fillet or drippings in µg
C_{COPC} = Concentration of COPC in µg/g fat in fillet or drippings
F = Percentage of fat in fillet or drippings
M_r = Mass of fillet or drippings in g

Studies that reported results solely on a toxicity equivalence (TEQ) basis were not included because actual changes in mass are obscured by weighting of individual congener results on the basis of toxicity.

For each study, **Table D-2** presents the reported or calculated percent mass loss values for three key COPCs (PCBs, DDx compounds, and dioxins and furans) by each of seven cooking methods with available data: 1) deep fry, 2) pan fry, 3) bake/roast, 4) broil/grill, 5) boil/poach, 6) microwave, and 7) smoke. The bake and roast cooking methods were considered sufficiently similar to be grouped for the purposes of this analysis, as were broil and grill (including charbroil), and boil and poach. The cooking methods with the most data points are broil/grill, bake/roast, pan fry, and deep fry. When all cooking methods are combined, the number of data points identified for each of the three COPCs is as follows: PCBs n = 79, dioxins and furans n = 12, and DDx n = 70. **Table D-3** presents mass loss results by cooking method for the three COPCs, as well as summary statistics and percentiles.

Analysis of Outliers and Extreme Values

An analysis was performed on the three combined cooking method data sets to determine if any individual data points may be statistical outliers or extreme values. Outliers and extreme values were defined using the Interquartile Range (IQR), which is equal to the difference between the 75th and 25th percentiles of the dataset. The IQR approach to the determination of outliers and extreme values has been referred to in the U.S. Environmental Protection Agency's (USEPA's) *Data Quality Assessment: Statistical Methods for Practitioners* (2006). Outliers and extreme values were defined as follows:

- Outliers: Those values that were less than (25^{th} percentile – 1.5 x IQR) or greater than (75^{th} percentile + 1.5 x IQR)
- Extreme values: Those values that were less than (25^{th} percentile – 3 x IQR) or greater than (75^{th} percentile + 3 x IQR)

The results of the outlier and extreme value evaluation are also presented in **Table D-3**. For each COPC dataset, those values determined to be outliers are highlighted yellow and those values determined to be extreme values are highlighted red. One value of 100% loss of dioxin following smoking (Zabik and Zabik 1995c) was identified as an extreme value. Two negative values for PCBs and five high end values for DDx compounds were identified as outliers. **Figure D-1** presents box and whisker plots with the outliers and extreme value identified by yellow and red dots, respectively.

Summary statistics and percentiles were calculated with and without the extreme values and outliers. As shown in **Table D-4**, midpoint values change only slightly when the extreme value and outliers are removed. **Figure D-2** presents the range and median cooking loss value by cooking method for each of the three COPCs (all values are included in **Figure D-2** with the exception of the extreme value of 100% loss of dioxin for smoking).

General observations include the following:

- Even when expressed on a consistent mass-loss basis, results are variable, with percent loss values ranging as high as 70 to 80% and as low as zero for the same COPC and cooking method
- For the study that reported an increase in mass after baking and broiling (Moya et al., 1998), the observations generally coincide with low initial COPC concentrations, and are likely an artifact of measurement error rather than a true net gain in COPC mass
- Median losses are generally in the range of 20 to 50% for typical cooking methods (i.e., pan frying, baking, broiling, deep frying), and consistent differences in mass loss between cooking methods are not apparent

- Based on the observation that the cooking loss results for each of the three categories of COPCs all fall into the same wide range, the case could be made for combining all studies into a single category of lipophilic organochlorinated compounds and assigning one cooking loss factor to the entire set of compounds
- Two studies examined the cooking loss of polychlorinated dibenzo-p-dioxins (PCDDs) and polychlorinated dibenzofurans (PCDFs) and coplanar PCB congeners in the same samples of fish under the same experimental protocols (Hori et al., 2005; Schecter et al., 1998). In each of these studies, the cooking losses of the PCDDs, PCDFs, and coplanar PCBs were nearly the same. Hence, the data indicate that these congeners comprise a group of compounds that should be assigned the same cooking loss factor.
- In keeping with USEPA's approach of differentiating cooking losses between COPC classes, a similar approach was taken here, and median and mean cooking loss values were computed for the three COPC classes
- Combining results for each COPC across all cooking methods and all data, the median (and mean) losses are: 30% (32%) for total PCBs; 50% (53%) for dioxins, furans, and coplanar PCBs; and 32% (34%) for DDx
- When statistical outliers and extreme values are removed, the median (and mean) losses change minimally: 30% (33%) for total PCBs; 48% (48%) for dioxins, furans, and coplanar PCBs; and 31% (31%) for DDx

There are a number of potential causes for the variability observed in the data, including differences in the specifics of the cooking methods (e.g., time, temperature), differences in fillet processing (e.g., trimming and thickness, part of body) and fillet geometry, variability in COPC concentrations between fish used within the same study, low initial COPC concentrations for some studies (e.g., less than 10-fold margin between concentration and the limit of detection [LOD]), and differences in extraction methods for raw and cooked tissue.

Another observation based on a review of the available data is that initial COPC concentration in the fish tissue does not appear to be a controlling factor when losses are reported on a mass basis. A relationship between skin removal or retention and cooking loss is not consistently apparent, although some studies did find greater loss with skin removal (Bayen et al., 2005; Salama et al., 1998; Zabik et al., 1979). Some studies suggest that higher internal temperatures and longer cooking times result in higher losses (Stachiw et al., 1998; Zabik et al., 1982). Lastly, while some data support a correlation between lipid loss and COPC loss during cooking (e.g., Bayen et al., 2005), analysis by others suggests that a loss of lipid is not consistently correlated with COPC loss (Wilson et al., 1998; Moya et al., 1998; Poston et al., 1995). In the analysis of PCB cooking loss studies conducted for the Hudson River HHRA, similar observations were reported (TAMS/Gradient 2000).

Combining data from various studies does involve several implicit assumptions:

- Behavior and analytical results for the different COPCs are sufficiently similar that data aggregation is legitimate (which is consistent with USEPA's approach)
- Two studies (Hori et al., 2005 and Schecter et al., 1998) provide evidence that cooking loss for dioxin-like PCB congeners may be more similar to that of PCDD/PCDF congeners than non-dioxin-like PCB congeners (see PCB values identified with an asterisk in **Table D-3**)
- Details of the preparation and cooking methods, such as the internal temperature, cooking time, tissue size, and geometry, are not critical
- Differences between fish species and lipid contents are not significant

While these assumptions introduce uncertainty, the available data are too limited for segregation and analysis of each these variables.

Summary

An updated review of the scientific literature identified 17 studies with relevant and appropriate data for quantifying the change in COPC mass in fish tissue as a result of cooking by several methods (deep fry, pan fry, bake/roast, broil/grill, boil/poach, microwave, and smoke). The studies address a variety of fish species, including striped bass, carp, trout, bass, catfish, perch, flounder, salmon, walleye, and bluefish. For the three COPCs included in the analysis (PCBs, dioxins and furans, and DDx compounds), a total of 79 data points were identified for PCB compounds (Aroclor and congener data), 70 data points were identified for DDx compounds, and 12 data points were identified for dioxin and furan compounds (PCDDs and PCDFs).

For each COPC, mass loss was demonstrated regardless of the cooking method used.[1] The amount of COPC mass loss was variable within and between studies, which is likely due to a variety of factors, such as cooking time, temperature, tissue preparation (skinning and trimming), fillet geometry, lipid content, initial chemical concentration, analytical methodology, and extraction efficiency, which are not consistently controlled for across the various studies. Despite the variability, the data are sufficiently consistent and robust to support inclusion of a quantitative cooking loss factor in the assessment of exposure dosage from consumption of fish. Because of the variability in the data, the median may be the most appropriate statistic for quantifying cooking loss, because it is the least affected by outliers and extreme values. As noted below, the essential approach used in the data reduction and selection is very similar to that used by USEPA in their derivation of cooking loss factors.

Based on analysis of the available data, estimates of cooking loss for each COPC are as follows:

- **For total PCB mixtures**, cooking loss ranged from no loss to 74% loss across the 14 studies with relevant data. Median losses by cooking method ranged from 25% (bake/roast) to 39% (smoke), with a median of 30% when all PCB data are combined regardless of cooking method.

[1] One study (Moya et al., 1998) did not show consistent PCB mass loss following baking and broiling of flounder; however, these results may be an artifact of highly variable initial PCB concentrations. Some studies have also speculated that negative values may be an artifact of incomplete COPC extraction from the raw tissue (Zabik et al., 1982; Sherer and Price, 1993).

- **For dioxins, furans, and coplanar PCBs**, cooking loss ranged from 28% to 63% across the four studies with relevant data. Median losses by cooking method ranged from 29% (boil/poach) to 57% (bake/roast), with a median of 48% when all dioxin and furan data (except the extreme value of 100%) are combined regardless of cooking method. Combining all dioxin, furan, and dioxin-like PCB congener data also results in a median of 48%.

- **For DDx,** cooking loss ranged from 3% to 80% across the 10 studies with relevant data. Median losses by cooking method ranged from 22% (boil/poach) to 45% (smoke), with a median of 32% when all DDx data are combined regardless of cooking method.

This analysis is consistent with how this issue has been evaluated in the past, both by USEPA and others (Bayen et al., 2005; Moya et al., 1998; Salama et al., 1998; Wilson et al., 1998; Sherer and Price, 1993; and Zabik and colleagues [1979, 1995a,b, 1996]). Additionally, the analysis reflects an updated data set, including several studies published since the USEPA's analysis for the Hudson River HHRA and the agency's fish consumption advisory guidance (USEPA, 2000).

Based on this updated analysis, the following cooking loss factors are supported for use in the BHHRA:

COPC	Cooking Loss Factor	
	10^{th} Percentile RME	Median CTE
Total PCBs	0.13	0.30
Dioxins, furans, and coplanar PCBs	0.29	0.48
DDx	0.10	0.32

The summary statistics for the full datasets were used because of the similarity of the statistics with and without outliers and extreme values. The exception to this is that the value of 100% for dioxins and furans was removed. For dioxin-like PCB congeners, available data support the use of the same cooking loss factor as that used for dioxins and furans. This consistency also makes sense when risks are assessed on the basis of a dioxin TEQ approach. While several of the pesticides included in the BHHRA (e.g., chlordane and it's isomers, dieldrin and hexachlorobenzene) were not specifically included in this analysis, it is expected that median cooking loss factors for other pesticides are in the same range as DDx (30% to 35%) based on studies where pesticides other than DDx have been evaluated (e.g., Zabik et al., 1995a,b, 1996).

Study	Chemical(s) evaluated	Species	Source of fish	Cooking method(s)	Was study method appropriate?	Do authors report loss on mass basis?	Was a quantitative estimate of mass loss possible?	Was study used in mass loss calculations?
Armbruster et al. 1987	PCBs	Striped bass	Long Island Sound	Bake, broil, pan-fry, poach, microwave, boil	Yes	No, concentrations before and after cooking reported on dry weight basis	No, data needed to convert results to mass basis not provided	No, but authors report a statistically significant reduction in concentration for 6 cooking methods combined
Armbruster et al. 1989	PCBs	Bluefish	Atlantic Ocean near Long Island Sound	Bake, broil, fry, poach	No, concentration change includes trimming and cooking	No, concentrations before and after trimming/cooking reported on dry weight basis	No, data needed to convert results to mass basis not provided	No, cannot distinguish loss due to cooking alone, but authors report an overall mean reduction of 67%
Bayen et al. 2005	PCBs, DDT	Salmon	Norway	Bake, microwave, boil, pan-fry	Yes	Yes	NA	Yes
Cichy et al. 1979	PCBs	Lake trout	Hancock, MI	Irradiate and broil	No, gamma irradiation used as well as broiling	Yes, percent mass loss due to irradiation and broiling	NA	No, cooking method not relevant to typical cooking practices
Ciereszko and Witczak 2003	PCBs	Carp	Poland	Boil, stew, pan-fry, deep-fry, microwave	Yes	No	No, fillet mass not provided (only % dry weight and lipid)	No
Domingo 2011	PCBs, PCDDs, PCDFs, PAH, HCB, PBDE,	*Review and summary of other published studies.*						No
Hori et al. 2005	PCDDs, PCDFs, and coplanar PCBs	Mackerel	Japan	Grill, boil, tsumire (chopped & boiled fish balls)	Yes	No; authors report “most isomers showed obvious downward trends”	Yes	Yes
Karl and Ruoff 2008	TCDD-TEQ and PCB-TEQ	Mackerel and Halibut	Bay of Biscay (mackerel) and Greenland (halibut)	Hot smoke	Yes	No	Yes	No, results presented on TEQ basis only; actual changes in concentrations obscured by weighting of results on basis of toxicity
Marmon et al. 2009	PCDDs, PCDFs, and PCBs	Herring	Baltic Sea	pH-shift processing	No	No	Possibly; mass balance data provided	No, method not relevant to typical cooking practice
Moses et al. 2009	Pesticides, PCBs, PBDEs	Sheefish	Northwest Alaska	Bake, dry, smoke	Yes	No	No, fillet weight data not provided	No
Moya et al. 1998	PCBs	Winter flounder	New Bedford Harbor, MA	Deep-fry, pan-fry, broil	Yes	Yes	NA	Yes, same data as Poston et al. 1995, which is the original study
Perello et al. 2010	PCDDs, PCDFs, PCBs, and PCDEs	Sardine, hake, tuna	Markets in Catalonia, Spain	Pan-fry, grill, boil, roast	No, raw and cooked data appear to be from different groups of fish; also, initial concentrations were close to or at LOD	No	Yes	No, calculating difference between concentrations in cooked fillet from one fish and raw fillet from another fish may not yield accurate estimate of loss, because initial concentrations may not have been similar; also, it is difficult to measure change due to cooking with very low initial tissue concentrations
Poston et al. 1995	PCBs	Winter flounder	New Bedford Harbor, MA	Deep-fry, pan-fry, broil	Yes	Yes	NA	Yes, same study as Moya et al. 1998
Puffer and Gossett 1983	PCBs, DDT, Benzo(a)pyrene	White croaker	Santa Monica Bay and Orange County, CA	Pan-fry	Yes	No	Yes, weight loss factor provided	Yes
Reinert et al. 1972	DDT, DDE	Yellow perch, bloaters	Lake Michigan	Pan-fry, bake, broil, smoke	Yes	No	Yes	Yes
Salama et al. 1998	PCBs	Bluefish	Massachusetts waters	Smoke, charbroil, microwave, pan-fry, bake	Yes	Yes	NA	Yes

Table D-1
Overview of Cooking Loss Studies
Benning Road Facility RI/FS Project
3400 Benning Rd, N.E., Washington DC 20019

Study	Chemical(s) evaluated	Species	Source of fish	Cooking method(s)	Was study method appropriate?	Do authors report loss on mass basis?	Was a quantitative estimate of mass loss possible?	Was study used in mass loss calculations?
Schecter et al. 1998	PCDDs, PCDFs, and coplanar PCBs	Catfish	Market in Binghamton, NY	Broil	Author (A. Schecter) reports that raw and cooked samples were all cut from the same fish samples, so concentrations are assumed to be similar	No	Yes, mean weight of catfish samples (n=4) before and after cooking provided	Yes, although some uncertainty associated with question of internal controls (use of same fish for uncooked and cooked comparison) and use of mean sample weights
Sherer and Price 1993	PCBs	*Review and summary of other published studies.*						No
Skea et al. 1979	Mirex, Aroclor 1254, DDT	Smallmouth bass, brown trout	Lake Ontario	Smoke, bake, broil, deep-fry	Yes	Yes	NA	Yes
Smith et al. 1973	Aroclor 1248 and 1254, DDT	Chinook, coho salmon	Manistee River, Michigan	Bake, poach, bake in bag	Yes	No	Yes, fillet weight and % fat in raw and cooked samples provided	Yes
Stachiw et al. 1988	2,3,7,8-TCDD	Carp	Saginaw Bay	Roast, charbroil	Study used "restructured carp fillet" (surimi), which involved mechanical deboning & processing of fillets	Yes	NA	Yes
Trotter et al. 1989	PCBs, pesticides	Bluefish	Massachusetts waters	Bake	Yes	No	Yes	Yes
Wang and Harrad 2000	PCBs	Salmon, trout	Not specified	Pan-fry	Yes	Yes, results corrected for mass loss	NA	Yes
Wilson et al. 1998	PCBs and DDT	*Review and summary of other published studies.*						No
Witczak 2009	PCBs	Herring, salmon, carp, trout, flounder, cod, loach	Market in Szczecin, Poland	Pan-fry	Yes	No	No, fillet weights not provided	No
Witczak and Ciereszko 2006	PCBs	Mackerel	Norwegian Sea	Smoke	No, sawdust used in smoker contained PCBs	No	No, fillet weights not provided	No, cross contamination from PCBs in sawdust is likely
Witczak and Ciereszko 2008	PCBs	Herring	Norwegian Sea	Smoke	No, sawdust used in smoker contained PCBs	No	No, fillet weights not provided	No, cross contamination from PCBs in sawdust is likely
Zabik et al. 1979	PCBs, DDT, dieldrin	Lake trout	Lake Superior	Broil, roast, microwave	Yes	Yes	NA	Yes
Zabik et al. 1982	PCBs, DDT	Carp	Saginaw Bay	Poach, roast, deep-fry, charbroil, microwave	No, the authors acknowledge issues with extraction from raw fillets	Yes	NA	No, cooking loss estimates from raw fillets in which extraction issues are noted will not provide accurate estimates
Zabik and Zabik 1995	Dioxin	Carp, salmon, trout, walley, white bass	Great Lakes	Bake, charbroil, deep fry, pan fry, salt boil, smoke	Yes	Yes	NA	Yes
Zabik et al. 1995a	PCBs, pesticides	Walleye, white bass	Lake Erie, Huron, Michigan	Bake, charbroil, deep fry, pan fry	Yes	Yes	NA	Yes
Zabik et al. 1995b	PCBs, pesticides	Carp, salmon	Lake Erie, Huron, Michigan	Bake, charbroil, deep fry, pan fry	Yes	Yes	NA	Yes
Zabik et al. 1996	PCBs, pesticides, PAH	Lake trout,siscowet	Lakes Huron, Michigan, Ontario, Superior	Bake, charbroil, salt boil, smoke	Yes	Yes	NA	Yes
Zabik and Zabik 1999	PCBs, PBBs, dioxin	*Review and summary of other published studies.*						No

Notes:
DDD - dichlorodiphenyldichloroethane
DDE - dichlorodiphenyldichloroethylene
DDT - dichlorodiphenyltrichloroethane
DDx - dichlorodiphenyltrichloroethane and its derivatives
NA - Not applicable.
PCB - polychlorinated biphenyls
PCDD - polychlorinated dibenzo-p-dioxins
PCDF - polychlorinated dibenzofurans
TCDD - tetrachlorodibenzo-p-dioxin

Table D-1
Summary of Studies Used for Mass Loss Calculations
Benning Road Facility RI/FS Project
3400 Benning Rd, N.E., Washington DC 20019

Study	Chemical(s) evaluated	Species	Percent Mass Loss						
			Deep Fry	Pan Fry	Bake/Roast	Broil/Grill	Boil/Poach	Microwave	Smoke

Notes:
(a) First value for frying in lard, second value for frying in corn oil.
(b) DDx mass loss was calculated by taking the average of mass loss values reported for DDD, DDE, and DDT (which are averages of replicates).
(c) Lake Erie
(d) Lake Huron
(e) Lake Michigan
(f) Charred and scored
(g) Lake Ontario
(h) Lake Superior
(i) Orange County
(j) Santa Monica

Acronyms:
DDD - dichlorodiphenyldichloroethane
DDE - dichlorodiphenyldichloroethylene
DDT - dichlorodiphenyltrichloroethane
DDx - dichlorodiphenyltrichloroethane and its derivatives
PCB - polychlorinated biphenyls
PCDD - polychlorinated dibenzo-p-dioxins
PCDF - polychlorinated dibenzofurans
TCDD - tetrachlorodibenzo-p-dioxin

50th Percentile	30	30	32	30	51	48
75th Percentile	42	43	41	40	59	55
90th Percentile	53	54	57	49	63	62
Maximum	74	74	80	58	100	63

Notes:

(a) - No extreme values were identified in the PCB data set; two negative values were identified as outliers.

(b) - No extreme values were identified in the DDx data set; five high-end values were identified as outliers.

(c) - One extreme value (100% loss) was identified in the dioxins and furans data set; no outliers were identified.
